

CHRONIC HEPATITIS IN THE MEDITERRANEAN THEATER

A NEW CLINICAL SYNDROME

COLONEL M. H. BARKER

MAJOR F. W. ALLEN

SANITARY CORPS, ARMY OF THE UNITED STATES

In a previous communication we have reported our observations on acute infectious hepatitis in the Mediterranean theater.¹ During the course of these studies it became apparent that certain patients failed to recover promptly, exhibiting symptoms and findings indicating persistent hepatic disease for prolonged periods of time with a tendency toward exacerbations and remissions. These cases present a sufficiently distinctive and uniform clinical picture to justify their consideration as a separate group or syndrome, which we have called chronic hepatitis. By the use of the term "chronic" we refer only to duration without implication regarding the nature of the pathologic process or the eventual prognosis. Although the existence of this condition has been recognized by others,² we believe that this is the first detailed clinical description based on adequate material.

Because of the large number of persons who have had infectious hepatitis during the last few years, the interpretation of residual symptoms and findings has become an important problem. It is often necessary to determine whether an organic lesion exists in such cases and, if so, whether further hospitalization and treatment will be beneficial. It is not possible to answer all of these questions with finality at the present time, but we believe that sufficient data are available to indicate a practical clinical approach to the problem.

It should further be pointed out that the term "syndrome" has been used advisedly, since it is probable that other etiologic types of hepatitis may present a similar clinical picture. Certain heretofore vague conditions common to civilian practice may well be clarified by these observations.

This work was made possible by the Surgeon's Office, Mediterranean Theater of Operations, and was greatly aided by many medical officers, nurses, enlisted personnel and other military personnel.

MATERIAL AND METHODS

This study is based on 76 patients obtained from among the unselected group of 431 cases of hepatitis previously described.¹ Many other examples of this condition were seen only in consultation. Although the clinical picture served as the primary basis for selection of cases, it was obviously necessary for statistical purposes to employ some arbitrary definition. Since the duration of the acute disease is both long and variable, the criticism must be avoided that we are simply dealing with the expected variants. Consequently we have chosen only those patients with evidence of active hepatitis four months or more after the onset (table 1). This is equivalent to a minimal period of five and one-half months from onset to recovery. An additional 79 patients were observed in the group of 431 who presented a similar picture but fell short of the foregoing criteria. Most of these were admitted in the acute stage, failed to recover in three months and so were evacuated to the United States. Many undoubtedly represent the same condition.

TABLE 1.—Duration of Active Infectious Hepatitis in 76 Cases of the Chronic or Persistent Type

	Months										Total % of Cases	Total
	4	5	6	7	8	9	10/12	13/24	25/36	36		
Number of cases												
Recovered.....	7	5	4	3	0	4	5	4	1	33	43.5	
Unrecovered....	2	9	7	4	9	6	3	3	0	43	56.5	
Total cases.....	9	14	11	7	9	10	8	7	1	76		

The final outcome in the unrecovered cases is not known.

The methods employed were the same as in our previous report.¹ Normal figures for the 5 mg. per kilogram sulfobromophthalein dye test were established during our Fort Custer, Michigan, study.¹ Fifty-five out of 56 normal soldiers who were given this test showed zero dye retention in one hour, and 1 man had 2 per cent retention. In order to allow for technical errors we have taken 3 per cent or more retention in one hour as abnormal. This is a conservative figure as judged by the literature.³

Microscopic observations on liver tissue obtained at biopsy as well as bacteriologic and virus studies were made by others on some of these patients. These results, when completed, will be published separately.

ETIOLOGY AND INCIDENCE

All of our cases gave a history consistent with acute infectious hepatitis either with or without jaundice at the onset of the disease. Evidence of activity of the hepatitis was always present, although sometimes minimal, during the interval between the onset and the

3. Mateer, J. G.; Blatz, J. I.; Marion, D. F., and MacMillan, J. M.: Liver Function Tests, *J. A. M. A.* 121:733 (March 6) 1943. Soffer, L. J.: Present Day Status of Liver Function Tests, *Medicine* 14:185 (May) 1935.

period of observation. This period was never less than three months. Jaundice occurred or recurred in 29 cases during the study period (table 2). Finally, all cases showed a positive exercise tolerance test,¹ indicating the existence of a potential recurrent acute hepatitis picture. In view of these facts it is only reasonable to suppose that a persistent virus infection is present.

TABLE 2.—*Prognostic Significance of a History of Jaundice During the Course of Chronic Hepatitis Prior to Admission and Jaundice at the Time of Observation*

Earlier in Course	Period of Observation	Number of Cases	Total Recovered	Per Cent Recovered
Jaundice	Jaundice	20	6	30
Jaundice	No Jaundice	21	8	38
No Jaundice	Jaundice	9	4	44
No Jaundice	No Jaundice	26	15	58

although there may also be additional etiologic factors of importance. As yet the bacteriologic studies have not been made to determine the presence of virus in the blood, liver or excreta.

It has been impossible to ascertain accurately the true incidence of this condition. It is probably quite variable. The great frequency (18 per cent) observed in our group was in part due to the poor nutritional condition of many soldiers at time of onset resulting from prolonged combat and in part to inadequate treatment of the acute disease. This figure, of course, is only for a particular group of hospital patients and does not indicate the number of acute cases in which the chronic form of the disease developed. During the last year the improvement of these factors has been associated with a reduction in incidence. The fact remains, however, that chronic hepatitis is much more common than generally suspected. It is too often unrecognized.

CLINICAL PICTURE

The clinical picture to be described is applicable to all phases of the chronic disease except a severe icteric relapse. Here the picture is the same as that of acute hepatitis except for severity, duration and prognosis.

History.—There is usually a history of an acute febrile illness consistent with acute hepatitis at the onset of symptoms. Occasionally the onset is insidious, as it may be in 10 to 15 per cent of acute cases. Following a period of illness, partial recovery occurs. Symptoms of the chronic disease then develop and persist with exacerbations and remissions. The patient may seek the doctor because of an exacerbation or simply because of persistent symptoms.

Symptoms.—The outstanding symptoms are lassitude, fatigue and mental depression of sufficient severity to be disabling in variable degrees. These are often most evident in the morning on awakening. The patient feels that he is "tired out" or wonders if "he isn't just neurotic." By forcing himself he is able to get through the day's work, but his mental and physical efficiency is low. Mental confusion and symptoms resembling an anxiety state are sometimes seen. True muscular weakness is unusual.

Of more diagnostic importance are those symptoms arising in the right upper quadrant, right lower chest and right lumbar region of soreness, aching, heaviness, fulness and sometimes actual pain. These symptoms are specifically aggravated by exertion and by jolting activity such as a rough automobile ride. Although this effect may be prompt in appearing, it characteristically persists for one or more days. Deep breathing

may produce a sharp, deep, poorly localized pain in the right side of the chest, and lying on the right side is often uncomfortable.

Low grade fever is occasionally present but unusual and suggests intercurrent infection. During the initial phase of an acute relapse, fever is frequently observed. Other common symptoms of chronic hepatitis are anorexia, dyspepsia, flatulence, intestinal cramps, intermittent mild diarrhea and headaches. Weight loss is common and occasionally severe, but many patients are well nourished. In a few instances attacks of severe generalized itching and formication have been seen, induced by heat and emotional states and associated with "goose pimples" and sometimes milium urticaria.

Physical Findings.—The liver is always enlarged and tender, but exercise may be necessary to make this finding manifest. Tenderness in the right costovertebral angle¹ and pain on fist percussion over the liver are usually present. There is often a latent period of about five seconds before this pain appears or reaches its maximum, which is a helpful differential point. The spleen is occasionally palpable and may be tender. Low, right sided, deep cervical adenopathy is often found during a relapse. The patient may or may not be jaundiced.

Laboratory Findings.—As would be expected, laboratory findings depend on the type of case and degree of activity of the hepatitis. In a severe icteric relapse the findings are the same as in the acute disease.¹ In other cases the laboratory is of less assistance, and often the diagnosis must be made on purely clinical grounds.

The sulfobromophthalein dye retention is abnormally elevated in 66 per cent of cases and has proved to be the most valuable test with which we have had experience (table 3). A normal test, however, does not rule out the diagnosis, although it does suggest that the liver damage is minimal. Retention of more than 9 per cent in one hour (or about 16 per cent in forty-five minutes) has almost always been associated with active hepatitis. A retention of 3 to 9 per cent in one hour means liver dysfunction but does not indicate the nature or whether the hepatitis is active or inactive. Serial tests, of course, are more informative than single determinations.

Bilirubinemia, a prompt direct qualitative van den Bergh reaction and bilirubinuria are significant when

TABLE 3.—*Significant Laboratory Findings in 76 Cases of Active Chronic Hepatitis*

	Nonicteric		Icteric		% of Total Abnormal
	Cases Tested	% Abnormal	Cases Tested	% Abnormal	
Sulfobromophthalein.....	44	61	26	69	67
	47	47	20	75	58
	40	20	20	41	29
	22	36	15	73	51

Patients are separated according to the presence of icterus during the period of observation. No sulfobromophthalein tests were done in the presence of clinical jaundice.

present but may be repeatedly absent. The erythrocyte sedimentation rate is often moderately elevated, but high readings suggest intercurrent infection. The blood picture is variable, although large atypical lymphocytes are often found. Anemia is unusual.

We have also had extensive experience with the Hanger test, serum alkaline phosphatase, serum globulin (table 3) and bilirubin clearance test. These procedures are often of value but are not consistently positive. The

additional use of serum amylase, serum albumin, colloidal gold and oral hippuric acid tests have not proved helpful. Results of urobilinogen determinations employing the usual methods have been too variable to be of aid. We have had insufficient experience with quantitative methods¹ to draw conclusions, but the preliminary results are encouraging.

An observation of practical interest is that the Graham-Cole test may reveal a dim or absent gallbladder shadow even when no jaundice is present. As the activity of the hepatitis subsides the gallbladder shadow gradually reappears or increases in density, as shown by repeated tests. There is also evidence obtained by Capt. Frank Parker Jr., M. C., that active nonicteric hepatitis may be associated with night blindness.

COURSE AND PROGNOSIS

Chronic hepatitis is characterized by a protracted course and a tendency to relapse, as shown in tables 1 and 4. How long active hepatitis may persist is not

TABLE 4.—Prognostic Significance of the Number of Distinct Exacerbations Prior to the Period of Observation, Including Those With and Without Jaundice

TABLE 5.—Rate of Recovery and Duration of Hospitalization in Chronic Infectious Hepatitis

Chronic Hepatitis	Total Cases	Per Cent of Total Discharged Recovered, Days After Admission				Recovered, Under Observation		Average Hospital Days, Recovered Cases
		42	50	70	84	No. of Cases	Per Cent	
Group N	46	4	9	15	22	15	33	72
Group R	30	12	40	50	53	18	60	54

Group N received the usual prewar therapy, while group R was treated by improved methods. Unrecovered cases were treated for three months before evacuation.

known, but our unrecovered patients still had active disease when evacuated to the United States after three months of hospitalization. Eight patients were active for more than one year and 42 for more than six months.

The course is variable, the degree of activity remaining fairly constant for months in some cases and fluctuating in others. Thus a given patient may feel fairly well as long as he performs only light duty, but increased exertion or an intercurrent infection may result in a reappearance or accentuation of symptoms. Inadequate treatment perpetuates the disease, although some patients gradually recover spontaneously over a period of months.

One of the most characteristic features of this syndrome is the prolonged treatment necessary to effect recovery. Thus, as shown in table 5, even with adequate therapy, 40 per cent of patients will still have active disease after three months, whereas in acute hepatitis the figure is 10 per cent or less. The duration of an acute icteric relapse is usually much longer than that of an acute primary attack of the same severity.⁴ Furthermore, in patients at bed rest or on minimal exercise subclinical activity of the hepatitis remains present for weeks following apparent recovery. This can be dem-

onstrated by employing the exercise tolerance test or its equivalent. Failure to appreciate this phenomenon will lead to erroneous decisions.

The immediate prognosis is good except in the presence of a severe relapse. Here one must take a more serious attitude than in an apparently comparable primary acute attack. The prognosis regarding clinical recovery and the time that will be required is always uncertain and difficult. Factors to be considered are age, duration of the disease (table 1), the number of relapses (table 4), the severity of the relapses as indicated by jaundice (table 2), the presence of removable precipitating factors as indicated in the next section, and the response to treatment. Although the appearance of jaundice is usually an unfavorable sign, sometimes a sharp icteric relapse may be followed by unexpectedly prompt recovery as if an adequate immunity had been produced. Failure to gain weight in definitely underweight patients is almost always associated with persistence of activity of the hepatitis. The importance of a past history of prewar "catarrhal jaundice," postvaccinal hepatitis or toxic hepatitis is difficult to determine. It is our clinical impression, however, that previous attacks of hepatitis frequently lead to a poorer prognosis.

Regarding the eventual prognosis, little is known. A few patients have been observed with ascites and spider nevi. Some of these improve and some develop a fatal liver failure. Cirrhosis is probably rare. However, it should be pointed out that on the basis of experimental evidence⁵ chronic or repeated liver trauma is more likely to result in permanent liver damage than a single severe insult. There is also considerable evidence in the literature that following infectious forms of hepatitis a large percentage of patients have a disturbance in bilirubin metabolism or excretion lasting for many years and probably of a permanent nature.⁶ Whether this finding indicates a benign dysfunction or whether it is usually associated with a more general disturbance of liver function is a matter of dispute. We can only say that clinical recovery is reasonably complete in the majority of our cases.

FACTORS ASSOCIATED WITH CHRONICITY AND RELAPSE

Exercise and Diet.—It has already been shown¹ that inadequate rest and a poor diet during the primary acute attack are important factors in the development of the persistent type of the disease. Seventy-five per cent of our chronic cases had less than four weeks' hospitalization in their initial acute attack and many had only ten days or none at all. It is probable that a poor nutritional status at the time the disease is contracted is an additional factor.

Infection.—Various intercurrent infections may prevent recovery from acute or chronic hepatitis or induce a relapse. This is particularly true of malaria, atypical pneumonia and dysentery. Acute tonsillitis, scarlet fever, acute pharyngitis, furunculosis and severe pyorrhea may play a similar role.

Tissue Trauma.—Traumatic wounds and surgical operations such as tonsillectomy or appendectomy are

Investigation* 21: 299, 1942. Altschule, M. D., and Gilligan, D. R.: Chronic Latent Hepatitis Following Catarrhal Jaundice, *New England J. Med.* 231: 315, 1944.

likely to be followed by a relapse. Inhalation anesthetics, especially ether, are of course an additional factor of considerable importance in such cases. Trench foot is very frequently associated with hepatitis, although the mechanism is not clear.

Alcohol.—When active hepatitis is present, excessive use of alcohol will definitely cause a relapse. We have no evidence, however, that alcoholic addicts are predisposed to hepatitis.

Spontaneous Relapse.—Neefe and his associates ⁷ have shown that in certain cases hepatitis may tend to run a cyclic course with several spontaneous exacerbations. This may explain the periods of increased activity of the disease which occasionally occur without cause in patients under apparently constant conditions.

Effect of Menses.—Usually beginning three to five days prior to the onset of menstruation, signs of increasing activity of the hepatitis may appear. In table 6 are a series of observations in such a case. On May 26 there was again a slight increase in findings preceding

side was uncomfortable. These symptoms became so severe that the patient consulted one of us on March 20, 1944 and the liver was found to be 6 cm. below the costal margin and very tender and was associated with tenderness in the right costovertebral angle. There was no jaundice, dark urine or anorexia, but intestinal cramps and an abnormal amount of flatus were present. A diagnosis of acute infectious hepatitis without jaundice, possibly recurrent, was made.

Against our best judgment the patient was kept in quarters and allowed to do light duty for six weeks. On March 31 the icterus index, serum phosphatase, Hanger test and hippuric acid excretion test were within normal limits. Symptomatic improvement occurred, so that by April 21 the chest pain and right upper quadrant pain had disappeared. Lassitude and fatigue were much less but still present. The liver was only 3 cm. below the costal margin and mildly tender. A sulfobromophthalein dye test showed 6 per cent retention in thirty minutes and 1 per cent in sixty minutes, and the Hanger test was negative. On May 31 symptoms were minimal; the liver edge was just palpable and not tender. No costovertebral angle tenderness was present.

Full duty was resumed in June; only minimal lassitude and fatigue were present. In July lassitude, fatigue and some right upper quadrant aching began to reappear, especially following strenuous exertion. These symptoms, associated with mental depression and symptoms of vasomotor instability, gradually increased until work was accomplished with great difficulty and with increasing inefficiency. Finally, on December 7 the patient was forced to enter the hospital because of the severity of the symptoms. Examination revealed a moderately tender liver 5 cm. below the costal margin with moderate right costovertebral angle tenderness. The qualitative and quantitative van den Bergh tests, the serum phosphatase and the Hanger tests were normal. The sulfobromophthalein excretion was 14 per cent in thirty minutes and 6 per cent in sixty minutes. The bilirubin clearance showed 16 per cent retention after three hours using a 200 mg. dose, a borderline figure, and a double oral Graham-Cole test revealed a very dim gallbladder shadow.

The patient was kept strictly in bed for four weeks and put on a high protein (250 Gm.) diet including about 2 pounds of rare steaks daily. On December 19 the liver was only 2 cm. below the costal margin and mildly tender. Symptoms were much improved. The sulfobromophthalein test showed 2 per cent retention in one hour. On Jan. 3, 1945 the dye retention was zero in one hour. After one month in bed only minimal symptoms were present. The patient stated that he hadn't felt so well for at least a year. The liver was slightly enlarged (3 cm.) but not tender. He was allowed up on minimal exercise for one month and then returned to duty.

Follow-up showed that there was mild increase in symptoms and in the physical findings during the subsequent three months following strenuous exertion, but improvement has continued and in August 1945 the patient is almost symptom free. The sulfobromophthalein test on March 20 was 1 per cent in one hour.

This case shows the prolonged course that chronic hepatitis can run. Whether the March 1944 attack was really the onset or whether it was in April 1943 we cannot say. No jaundice was ever observed. Recovery did not occur until after a two month period of hospitalization, and it is still not certain that it is complete. The correlation between the objective findings and the symptoms suggestive of a psychoneurosis is striking and indicates that the latter are on an organic basis.

CASE 2.—A white soldier aged 19 was admitted on March 2, 1944 because of fever, nausea and vomiting of four days' duration. On Nov. 11, 1943 he had a similar attack associated with "coeca-cola" colored urine but no definite jaundice. He was not hospitalized. The acute symptoms subsided in about a week, but since then he had experienced pronounced lassitude, easy fatigue, anorexia and fat intolerance. He continued in combat but was able to perform his duties only with the

TABLE 6.—Effect of Menses in Chronic Hepatitis Without Jaundice

Determination	Onset of Menses May 5 at 5 P. M.

Symptoms.....	2+	—	1+	..	3+	1+	2+

the next menses, which occurred June 4, but the hepatitis was in a less active stage. Fluid retention associated with the menses is undoubtedly an important factor, but there is probably also an increase in activity of the hepatitis, as shown by the changes in sulfobromophthalein retention.

REPORT OF CASES

The following cases serve to demonstrate some of the foregoing points:

CASE 1.—A white medical officer aged 38 was admitted because of progressively increasing lassitude and fatigue for the previous five months. He had received yellow fever vaccine in March 1942 and developed extreme fatigue three months later with anorexia and right upper quadrant pain associated with a large and tender liver. No jaundice or dark urine was observed, but the officer was not hospitalized. Exercise was restricted, and symptomatic recovery occurred in about three weeks. In April 1943, in the Italian theater, the patient had a rather prolonged bout of atypical pneumonia. Convalescence was slow, and residual fatigue persisted. The liver was found to be somewhat enlarged at this time, but no special attention was paid to it.

About March 1, 1944 the patient developed increasing fatigue, lassitude, mental depression, right lumbar and right upper quadrant pain and deep pain in the right chest on breathing. Because of the latter symptom a chest plate was requested but was normal. There were also attacks of generalized pruritus, occasionally accompanied by military urticaria precipitated by heat and emotional states. Lying on the right

7. Neefe, J. R.; Stokes, J., Jr.; Reinhold, J. G., and Lukins, F. D.: Hepatitis Due to the Injection of Homologous Blood Products in Human Volunteers, J. Clin. Investigation 23: 836 (Sept.) 1944.

greatest effort. There was no previous history of jaundice. He had not received yellow fever vaccine.

On admission the liver was very tender and enlarged 5 cm. below the costal margin. Moderate jaundice was present. The next day the icterus index reached 44, the maximum elevation. The serum globulin was 3.3 Gm. per hundred cubic centimeters, alkaline phosphatase was 4.5 Bodansky units, the Hanger test was 2+/3+ and the oral hippuric acid excretion test was 2.9 Gm. Repetition of this last test the following day after 15 Gm. of aminoacetic acid gave a result of 3.6 Gm.

One month after admission the icterus index was normal, the liver was only slightly enlarged (3 cm.) and only slightly tender, and symptoms were much improved but the sulfobromophthalein dye detention was 36 per cent in thirty minutes and 18 per cent in sixty minutes. After two months' total bed rest the liver was not definitely tender, only borderline in size (2 cm.) and symptoms were minimal, so the patient was allowed out of bed. Following thirteen days on an ambulatory status an exercise tolerance test was started. By the morning of the third day the liver had become definitely tender and had increased in size to 4 cm. below the costal margin, and tenderness had appeared in the right costovertebral angle. Lassitude, fatigue and anorexia became evident and a constant ache developed in the right upper quadrant. The sulfobromophthalein retention was 22 per cent in thirty minutes and 17 per cent in sixty minutes.

The patient was returned to bed. The aforementioned findings and symptoms remained for about ten days before beginning to subside. A check sulfobromophthalein test was 38 per cent in thirty minutes and 18 per cent in sixty minutes.

The patient was evacuated to the United States because of obvious activity of the hepatitis after three months' hospitalization.

This case demonstrates the development of the chronic state due to lack of treatment in a mild acute hepatitis. Such initial attacks are often diagnosed as an upper respiratory infection. The subsequent symptoms may be severe but not totally disabling and are frequently looked on as functional by the medical officer. Most important is the apparent clinical recovery at bed rest and the demonstration by means of the exercise tolerance test of persistent activity after more than two months of treatment. One would expect a primary acute hepatitis to have recovered by this time.

DIAGNOSIS

The diagnosis of chronic or relapsing hepatitis with jaundice is not difficult if the past history is kept in mind. Obstructive, hemolytic and spirochetal forms of jaundice and toxic hepatitis must be ruled out. This subject is well covered in the literature. Active hepatitis must not be diagnosed on the basis of low grade elevations of serum bilirubin alone (2.0 mg. per hundred cubic centimeters or under) since many patients clinically recovered from infectious hepatitis may have such findings for years.⁶ If other evidence of activity is not present the exercise tolerance test must be employed.

In the absence of jaundice, diagnosis becomes more difficult, especially if the initial acute attack was also non-icteric. In the latter case the physician must be unusually cautious in making this diagnosis and the picture must be very clearcut, else patients will be unnecessarily invalidated and other conditions will be missed.

A definitely enlarged and tender liver must be found and there must be an abnormal exercise tolerance test or its equivalent. If such liver findings are already present, exercise is, of course, unnecessary. There should be a history of an acute attack of hepatitis preferably within a year, with residual symptoms suggesting at least mild activity. The presence of characteristic symptoms which are aggravated by exertion or by

jolting activities is important. Abnormal laboratory findings are valuable corroborative evidence, although not absolutely necessary. An elevated sulfobromophthalein retention or an increased serum bilirubin is to be especially desired. A dye retention of 5 per cent in one hour or more is desirable for diagnosis in cases that have never been icteric. This finding alone, of course, indicates only liver dysfunction and does not constitute a basis for the diagnosis of active hepatitis.

It is also necessary to consider other etiologic types of hepatitis. Acute alcoholic hepatitis, chronic brucellosis and toxic hepatitis as from carbon tetrachloride may present somewhat similar pictures especially from the laboratory point of view. The history and, in certain cases, specific tests will usually clarify the situation.

The determination of liver size and tenderness on physical examination is not easy and because of its importance warrants discussion. Percussion of the upper border is essential in order to rule out ptosis. To be certain of the location of the lower border, the actual edge should be felt. Frequently, light palpation will be more satisfactory than the usual deep variety, since the patient with a tender liver is likely to stop inspiring when the edge meets the physician's hand. When the edge is not definitely palpable, percussion is the most reliable guide. In doubtful cases a roentgenogram may be helpful. It must be remembered that the location of the normal liver edge during deep inspiration is variable and that it is often readily felt 1 cm. below the costal margin. One can be certain of moderate degrees of enlargement only when definite changes in size occur. Finally, the normal liver is somewhat tender if the edge is "flipped." Clinical judgment is necessary for proper evaluation.

The most frequently encountered conditions that have had to be differentiated from this syndrome are as follows:

Chronic Diarrhea and Irritable Bowel.—Because of the frequency of intermittent diarrhea in chronic hepatitis these conditions are readily confused. Bowel tenderness in the right upper quadrant can be distinguished from hepatic tenderness by noting that in the former case the tenderness is more pronounced during expiration, whereas in the latter case it is more pronounced during inspiration. Percussion tenderness may be present in both instances.

In uncomplicated chronic diarrhea there is ordinarily no abnormality in liver findings or in liver function tests. However, in amebiasis and possibly certain other types of chronic dysentery, liver disease may occur. Furthermore, it is not unusual to find infectious hepatitis and amebiasis in the same individual. Specific therapy should be employed and the hepatitis evaluated after the amebiasis is under control.

Duodenal Ulcer and Chronic Cholecystitis.—The not infrequent finding of an irritable duodenal bulb at x-ray examination in cases of chronic hepatitis has led to occasional confusion with duodenal ulcer. It is probable that a duodenitis is present. Because of the symptomatology and an absent or dim gallbladder shadow with the Graham-Cole test the diagnosis of chronic cholecystitis may be erroneously made. In the case of infectious hepatitis, however, this test will become negative as recovery progresses. In our experience the exercise tolerance test, liver function tests and history have usually sufficed to differentiate these conditions.

Psychoneurosis.—This is the most frequent diagnostic error. Confusion arises because of the mental depres-

sion, the superficially suggestive symptomatology and the usual psychoneurotic factor present in any prolonged illness. If objective findings are relied on, the diagnosis is not difficult and the only real problem is the extent of the functional factor if any. If active hepatitis is present, caution must be exercised in making an additional diagnosis of psychoneurosis because bed rest will frequently relieve all symptoms.

Chronic Malaria.—Untreated chronic malaria may present a picture very similar to that of chronic hepatitis. Anemia, a high erythrocyte sedimentation rate, reticulocytosis and pronounced splenomegaly are suggestive findings. Since these two conditions frequently occur together, it is necessary to employ the usual diagnostic criteria for hepatitis after specific antimalarial therapy has been completed.

MANAGEMENT

The first consideration is the establishment of the diagnosis. In this connection it should be made clear that ordinarily the patient with active chronic hepatitis who comes to see the doctor and has been on duty or at work has evident objective findings. An exercise tolerance test under such circumstances is unnecessary and undesirable and should be reserved for cases in which the diagnosis is in doubt. If active hepatitis has been established the patient should be put to bed. Lavatory privileges can be allowed except to the seriously ill, but otherwise strict rest must be enforced. The patient should be placed on a well balanced, high protein (250 Gm.), high caloric diet as in the acute disease.¹ The most desirable proteins are meat, milk, cheese and eggs. The question of fats is still not settled, but meat fats are not well tolerated. Two ordinary polyvitamin capsules can be given daily. Treatment is otherwise symptomatic.

The effectiveness of this therapeutic regimen is shown for the present series in table 5. Group N, seen during the spring of 1944, received the generally accepted therapy of a high carbohydrate (350 Gm.), low fat (40 Gm.) and average protein (85 Gm.) diet with only moderate bed rest, whereas group R, studied during the summer of 1944, received a high protein (250 Gm.), high carbohydrate (350 Gm.) and low fat (40 Gm.) diet accompanied by strict and adequate bed rest. The better results in the R group are apparent and we believe significant, although the naturally variable course of this condition suggests caution in drawing final conclusions. It will be noted that fat was low in both diets, so that the effective nutritional factor must have been either the increased protein or the greater caloric intake which resulted from increased palatability. The more strictly enforced bed rest in the R group was also most effective.

It is important to search for any complicating conditions or foci of infection such as malaria, amebiasis or apical abscesses, especially if recovery is slow. Tonsils should not be removed unless severely infected, owing to the danger of precipitating a relapse.

The decision as to when a patient should be allowed up is difficult. Conservatism is obviously important. The criteria employed for acute hepatitis¹ are adequate, provided the patient is kept in bed for two or more additional weeks. The patient must be carefully followed during the ambulatory period and then for another two weeks if actually exercising or for perhaps four weeks if simply returning to work. If findings and symptoms recur, bed rest must be resumed.

INACTIVE HEPATITIS

We have reserved the term inactive hepatitis for patients who have objective evidence of liver disease or dysfunction and a past history of acute hepatitis but who have a normal exercise tolerance test. A large nontender liver or an increased sulfobromophthalein retention has been accepted as satisfactory evidence. Low grade elevation of the serum bilirubin might also be acceptable. Symptoms are limited to dyspepsia, gas, fat intolerance and slight fatigue, none of which are disabling. Since neither exercise nor rest has any significant effect on the clinical or laboratory picture, hospitalization or bed rest is unnecessary. It is therefore of great practical importance to distinguish this condition from active hepatitis. Furthermore, with the exception of the small group mentioned later, these patients are not disabled. The presence of additional symptoms of hepatitis suggests either activity of the process or a functional element.

Seventy-four per cent of all acute cases in the N group that recovered (81 cases) fell into the inactive category at the time of discharge to duty as judged by the sulfobromophthalein test. Thirty-two per cent of the total had a dye retention of from 5 to 9 per cent in one hour, and in 12 per cent it was 3 or 4 per cent in one hour.

TABLE 7.—Gradual Improvement in a Case of Inactive Hepatitis Without Treatment

	Jan. 1	April 19	29	May 6	13	20	27	June 3	Dec. 3
Sulfobromophthalein, per cent retention in 30/60 minutes.....	..	15/3	16/5	22/7	9/5	12/6	18/8	9/5	9/2
Liver size, fingerbreadths below costal margin...	..	2F	1-2F	2-3F	1-2F	1-2F	1-2F	1-2F	1-2F
Onset of acute hepatitis	X								

The average period of hospitalization in this group was sixty-six days. It is evident that complete recovery from infectious hepatitis usually requires at least two months and that inactive hepatitis represents the last stage in healing.

The eventual prognosis of inactive hepatitis is not known, but from a clinical point of view it appears to be excellent. In some cases progressive improvement in findings may continue to occur for many months even though the patient is on duty, as shown in table 7. This officer returned to work about April 22, explaining the increase in abnormal findings following the first test. He remained on duty throughout the period of these observations without symptoms and without liver tenderness. We have seen many similar cases in which findings were still present at the end of a year.

A special group of cases must be mentioned, fortunately small in number, who fall into the inactive category. In addition to the usual picture they show decided weight loss, true weakness, fatigue and gastrointestinal symptoms. They are often repeatedly hospitalized without benefit. In 1 instance the condition has remained static for three years. It is probable that these cases represent a relatively severe form of inactive hepatitis.

Treatment of the ordinary case of inactive hepatitis is unnecessary. In fact it is desirable to encourage normal activities so as to avoid mental fixation on the residual symptoms. A continuation of the dietary regimen, if feasible, can of course do no harm. In the special group mentioned, the diet is probably important and

should be continued for six to twelve months or until recovery occurs. Physical exertion should be limited to light duties.

COMMENT

We have referred advisedly to chronic hepatitis as a syndrome. It is believed that our cases represent a single disease entity, but it is likely that other etiologic types of hepatitis may present a similar clinical picture. The etiology in our group is, as yet, not entirely clear. It appears probable that the infectious agent of the acute disease is still present and that the liver lesion is at least in part of an infectious nature. The frequent occurrence of icteric relapse even though jaundice was absent in the initial acute attack is strong evidence for this point of view. There is no reason to believe that nonicteric cases differ at all from those with jaundice except as regards severity. A past history consistent with acute hepatitis was always obtained. Furthermore, the abnormal clinical and chemical response to exercise uniformly present suggests that under proper circumstances any of these patients are capable of developing an icteric relapse. Thus, persistent infection appears to be one of the chief etiologic factors. It is possible that reinfection may be of importance in some cases. Recovery is probably prevented or delayed by inadequate rest, poor nutrition and intercurrent infection. Final judgment must await demonstration of the infectious agent.

A direct nutritional effect on the liver⁸ is probably an etiologic factor in certain cases. Its importance is difficult to assess. The fact that chronic hepatitis can occur in apparently well nourished persons and in patients on the recommended hepatitis diet indicates that this explanation of chronic hepatitis is not always valid. The possibility of a purely nutritional liver lesion must be considered and may well occur, but it is very unlikely that this is the cause of the cases described in this report.

The relationship of the symptomatology here described to liver disease has not been previously recognized. The correlation between symptoms and the laboratory and clinical evidence of activity of the hepatitis is so definite that it is only reasonable to assume a causal relationship. It is possible that other etiologic types of hepatitis may be associated with a similar clinical picture. Chronic brucellosis and protracted convalescence in infectious mononucleosis may fall in this category as well as certain cases of so-called functional bowel disorders. It may be that certain symptoms in these conditions hitherto unexplained will prove to be related to a form of hepatitis.

SUMMARY

1. The syndrome of chronic infectious hepatitis is a reasonably common condition of a disabling nature.
2. The most characteristic and diagnostic feature is the increase in physical findings, symptoms and laboratory evidence of liver dysfunction produced by exercise. Frequently a patient appears to have recovered while on minimal exercise, but an increase in physical activity will cause the clinical syndrome to reappear.
3. The essential treatment is adequate bed rest and a high protein diet.
4. There is an important distinction between active and inactive hepatitis. The latter group includes cases with objective evidence of liver disease and a normal reaction to exercise. Symptoms are not disabling, and no treatment is necessary.

PSEUDO-GAS GANGRENE OF THE HAND

A. DANIEL RUBENSTEIN, M.D.

District Health Officer, Massachusetts Department of Public Health;
Assistant in Epidemiology, Harvard School of Public Health

I. R. TABERSHAW, M.D.

Director, Division of Industrial Hygiene, Alabama Department
of Public Health

AND

JOAN DANIELS, B.S.

Assistant Bacteriologist, Massachusetts Department of Public Health
BOSTON

Aeriform infections of the hand of industrial origin, unrelated to the usual gas producing anaerobes, have not been previously described in this country. Recently 3 cases presenting such a syndrome were reported from two plants where an alloy containing 90 per cent magnesium was being utilized in manufacturing processes. Gas bacillus infection was the initial diagnosis in each instance and therapy with gas gangrene antitoxin had been instituted. Bacteriologic studies did not, however, reveal the presence of gas forming anaerobes. In all 3 cases the appearance of the infection followed an accidentally incised wound received shortly after handling magnesium. Fortunately radical surgical procedures were not performed.

Study of the possible hazards associated with the use of magnesium was stimulated by the recently increased demand for this metal throughout the aircraft manufacturing industry. These studies disclosed that an alloy containing at least 89 per cent magnesium, when introduced beneath the skin of rats, produced macroscopic tumor masses.¹ This phenomenon occurred when as little as 10 mg. of powdered magnesium was injected.² These observations were confirmed by Schulz and Walter.³ Both groups of workers found that at least a portion of the gas produced in this manner was hydrogen.

It has been known for some time that, in human beings, contact of magnesium with body fluids and tissues stimulates the evolution of gas. Seelig⁴ in 1924 noted that gaseous cysts formed about magnesium when this metal was used as suture material in certain operative procedures. The more recent investigations demonstrated that powdered magnesium produced larger tumors than spicules of this metal.² Subcutaneous injection of aluminum and alloys containing less than 89 per cent magnesium was not followed by formation of gas in animal tissues.¹

PURPOSE AND METHODS

The purpose of this study is to present the clinical manifestations of a syndrome which may simulate gas gangrene. The nature of the causative agent is unknown. However, bearing in mind the evidence acquired by animal research and the occurrence of all 3 cases in an environment where finely powdered magnesium was plentiful, the possibility is suggested that this metal constitutes a significant factor in the etiology. Irrespective of its cause, the signs and symptoms present a well defined clinical entity which must be differentiated from gas bacillus infections. Confusion of these conditions may give rise to serious consequences.

2. Meek, S. F.; Prendergast, J. J.; Harrold, G. C., and McCord, C. P.: Physiological Action of Metallic Magnesium, *J. Indust. Hyg. & Toxicol.* 24: 142-147 (June) 1942.

3. Schulz, R. Z., and Walter, C. W.: Magnesiumous Pneumogranuloma, *J. Indust. Hyg. & Toxicol.* 24: 148-153 (June) 1942.

4. Seelig, M. G.: Study of Magnesium Wire as Absorbable Suture and Ligature Material, *Arch. Surg.* 8: 669-677 (March) 1924.

In addition to the clinical description of the syndrome, certain bacteriologic studies were performed. Cultures were taken of the lesions, of cutting oils and of tools and machines used by the patients. Samples of powdered magnesium found on the lathes and other machines were also examined bacteriologically.

Cultures were grown both aerobically and anaerobically. After isolation in pure culture, identification of individual organisms was carried out as completely as possible.

RESULTS OF BACTERIOLOGIC STUDIES

Not a single organism of the gas forming anaerobes was isolated either from lesions of the patients or from materials and tools used at the plants. A *Staphylococcus aureus* was recovered from the operative wound of patients 1 and 3. Cultures of 1 of these (patient 3) had been negative until several incised areas became secondarily infected. Cultures from the incision of the third patient were negative both at operation and during the subsequent course.

A greater variety of organisms was cultured from the soluble than the insoluble oils, as shown in the table.

Bacteria Isolated from Machine Shop Materials

Material Cultured	Organism Isolated	Number of Specimens from Which Isolated
Insoluble oil (4 specimens)	<i>Staphylococcus albus</i>	2
	Gram negative chromogenic bacilli (orange)	1
	Gram positive nonsporulating bacilli	1
	Aerobic spore-bearing bacilli	1
Soluble oil (4 specimens)	Gram negative lactose-fermenting bacilli	3
	Gram negative fluorescent bacilli of the family <i>Pseudomonadaceae</i>	3
Magnesium (2 specimens)	Aerobic spore-bearing bacilli	2
	<i>Staphylococcus albus</i>	1
	Gram negative lactose-fermenting bacilli	1
	<i>Streptococci</i> , green producing on blood agar and fermenting lactose and mannite	1
Table grinding mill	Aerobic spore-bearing bacilli	1
	Gram negative lactose-fermenting bacilli	1
Sarno lathe	Gram negative lactose-fermenting bacilli	1

Bacteria belonging to the family *Pseudomonadaceae* were the most frequent contaminants of the soluble oils. Lactose fermenting bacteria were also demonstrated in these oils. Several varieties of bacteria were recovered from the insoluble oils.

REPORT OF CASES

CASE 1.—History.—F. O., a white woman aged 32, admitted to the hospital on Nov. 13, 1943 complaining of swelling and a "feeling of numbness" of the right ring finger and hand, had been perfectly well until 12:50 a. m. on the morning of the day of admission.

While she was employed as a lathe operator, a magnesium adapter with which she was working slipped and lacerated the dorsum of the right ring finger.

The laceration, which occurred over the dorsum of the distal phalangeal joint, was about one-half inch in width and bled freely. First aid was administered by the plant nurse. At 3 a. m. the patient noticed that the finger had swollen considerably and that the swelling had spread to the back of the hand. At 2 p. m. on the same day, alarmed by the swelling and dull pain in the finger and hand, she consulted her physician. By this time the swelling involved the entire dorsum of the hand. The physician advised immediate hospitalization.

The patient had been working for some time with an alloy containing 90 per cent magnesium. Not infrequently her hands came in contact with fine particles of this material, which were difficult to remove because of the presence of cutting oils.

Her temperature on admission was 99 F. and pulse rate 100. Examination of the right hand revealed considerable swelling

of the dorsum of the ring finger and hand, where there was crepitation. On palpation of the hand there was a peculiar sensation described by the examining physician as "crushed egg shells in a cloth bag." Physical examination was otherwise negative.

Laboratory examination revealed a red blood cell count of 4,100,000 and hemoglobin 84 per cent (Sahli). The white blood cell count was 6,600 and the blood smear revealed polymorphonuclears 52 per cent, lymphocytes 40 per cent, monocytes 3 per cent and eosinophils 5 per cent. Urinalysis was negative. Cultures of the hand taken at the time of operation revealed a hemolytic *Staphylococcus aureus* and a gram negative bacillus.

Course.—With a diagnosis of gas bacillus infection, operation was performed at 6 p. m. Although amputation had been suggested by a consultant, surgery was limited to two linear incisions over the dorsum of the hand, each about 4 inches in length. There was a perceptible decrease in the amount of swelling after the incision. The wound was irrigated with peroxide and diluted solution of sodium hypochlorite. The patient received 10,000 units of tetanus antitoxin on admission and, in addition, 45,000 units of gas gangrene antitoxin over a period of three days. She also received a total of 23 Gm. of sulfathiazole in five days.

Postoperatively the temperature rose to 101.6 F. and remained elevated for two days, following which it was normal. The patient complained of pain in the hand and wrist. There was some stiffness of the fingers. On November 22, under sodium pentothal anesthesia, the edges of the wound were approximated and closed with Michel clamps. Except for some residual stiffness of the third, fourth and fifth fingers of the right hand, convalescence was uneventful.

CASE 2.—History.—J. A., a white man aged 23, married, admitted to the hospital on Feb. 28, 1944, complained of pain and swelling of the left ring finger and hand. About 2 p. m., while reaming a coil on a lathe, he lacerated the tip of the left ring finger. He had been tooling objects made of 90 per cent magnesium. During the course of his work, his hands and the lathe usually became covered with fine magnesium particles. Ten minutes after the laceration, he noted that his finger had become swollen and painful. He could not remove a ring worn on the cut finger. The pain became so severe that he had to leave his work. The plant nurse suggested that he consult his family physician. At 2:40 p. m., when he visited his doctor, the swelling had progressed to the dorsum of the hand as far as the wrist; his hand was now as large as a "boxing glove." The family physician made a tentative diagnosis of gas bacillus infection and advised hospitalization.

The temperature on admission was 99.2 F. and the pulse rate 100. The physical examination revealed that the patient, who was fairly well developed, was in a great deal of pain. Examination of the hand revealed a small laceration over the tip of the left ring finger. The finger and hand were swollen to the wrist. There was crepitation over the dorsum of the hand and ring finger.

Laboratory Examination.—The red blood cell count was 3,900,000, hemoglobin 78 per cent (Sahli) and white blood cell count 16,700. The blood smear showed polymorphonuclears 93 per cent, lymphocytes 7 per cent. Urinalysis was negative. Blood cultures on February 29 and March 1 were negative. Cultures taken of the hand at operation revealed no growth.

Course.—The patient was given 30,000 units of gas gangrene antitoxin and was started on sulfathiazole (total dosage 12 Gm. in forty-eight hours). Operation was performed at 5 p. m. on the day of admission. Three linear incisions were made over the dorsum of the hand extending from the knuckles to just above the wrist. An additional linear incision was made on the ventral surface of the palm, and "through and through drainage" was instituted. There was a definite decrease in the amount of swelling immediately after incision.

During the subsequent course there was no evidence of spread beyond the operative incision. The temperature rose to 103 F. immediately after the operation and remained elevated for forty-eight hours. Thereafter, except for a slight rise to 99 F. on the fifth hospital day, it was normal. The pulse rate was

about 100 for five days. On March 2 the patient developed an infection of the mucous membrane of the mouth and tongue. On March 6 the drains were removed. Five days later, under anesthesia, the wounds were closed with Michel clips. Convalescence was uneventful. The wounds healed without difficulty. The patient was discharged from the hospital on March 18, 1944.

CASE 3.—History.—M. S., a white man aged 38, married, a machinist, admitted to the hospital on Sept. 23, 1944, complained of pain and swelling of the left hand and arm. About 6:45 p. m., while at work, a file slipped and punctured his left thumb. For two or three hours prior to the accident he had been "setting up" machines on which objects made of a 90 per cent magnesium alloy were being tooled.

The point of the file penetrated the skin, and there was a moderate amount of bleeding. Despite the injury, he continued at his work. About ten minutes later he noticed a feeling of numbness of the hand. Tapping the back of his left hand with the right caused a peculiar sensation which he described as "air in a football." When he consulted the plant nurse for first aid, she also expressed the opinion that there was air beneath the skin and advised that he see his doctor. He arrived at his physician's office about 7:45 p. m., approximately one hour later. At this time the swelling had progressed beyond the dorsum of the hand to the arm. His physician advised immediate hospitalization. The swelling continued to spread; at 10:30 p. m. it had reached a point 2 inches below the shoulder.

The temperature on admission was 98.8 F., the pulse rate 80 and the respiratory rate 16. Physical examination showed that the patient was well developed and well nourished and that his general appearance was good. The dorsum of the left hand, thumb and arm was swollen. There were tenderness and crepitation throughout the arm. In some areas bubbles beneath the skin felt "as large as eggs." Except for the palm, there was crepitation of the entire left extremity.

Laboratory Examination.—The red blood cell count on September 24 was 4,050,000, hemoglobin 85 per cent (Sahl). The white blood cell counts rose from 10,000 on September 23 to 47,000 on September 29 and gradually dropped to 7,600 on October 9. The blood smear showed a gradual rise of polymorphonuclears from 76 per cent on September 23 to 95 per cent on September 30 and then gradually dropped to 50 per cent on October 9. Blood cultures on September 27, September 30 and October 4 were negative. Urinalyses were negative except that occasionally there was the slightest possible trace of albumin. Cultures of the hand at operation revealed no growth. On October 4 cultures of the wound were positive for hemolytic *Staphylococcus aureus*.

Course.—Operation was performed at 11 p. m. (four and one-half hours after injury). Under sodium pentothal anesthesia numerous incisions (about twenty-two) were made from a point just below the shoulder to the dorsum of the hand. The incisions varied from 2 to 6 inches in length and extended through the skin, fat and superficial fascia to the muscles and tendons. The surgeon noted very little resistance to the scalpel. After incision the swelling subsided to a great extent. Dakin tubes were inserted into the wounds and kept in place by sutures. The wounds were irrigated with peroxide.

The temperature remained normal until the second postoperative day, when it rose to 100 F. and remained elevated until September 27. Subsequently the temperature remained normal until October 5, when there was a slight elevation which lasted about forty-eight hours. The pulse was not high throughout the entire course.

During the first three days of his hospital stay the patient received 30,000 units of gas gangrene antitoxin. On September 23 he was given 30,000 units of penicillin and thereafter he received 20,000 units, intramuscularly, every three hours until September 28. On September 29 the dosage was reduced to 10,000 units every three hours. Sulfadiazine therapy was instituted on September 24, and the patient received 1 Gm. every four hours until September 27.

On September 29 the patient developed herpes of the nose, lips and left cheek. Several of the wounds had become secondarily infected, and there was a moderate amount of purulent drainage. On October 7 all drains had been removed and, under sodium pentothal anesthesia, the wounds were closed with Michel clips. Recovery was uneventful thereafter, and the patient was discharged on October 18 with full use of his arm.

COMMENT

The similarity in the symptomatology and clinical course of the 3 cases is apparent. Of interest is the rapidity with which swelling and crepitation appeared subsequent to the rather trivial injury sustained by each patient. In all 3 cases swelling was noted after an interval of only ten minutes. In 2 cases (2 and 3) crepitation was found by the attending physician one hour after injury.

Of the 3 patients 2 (F. O. and M. S.) had been employed in the same plant. In each instance a superficial laceration had occurred after handling powdered magnesium (a 90 per cent alloy). In 1 case the injury was caused by an object made of this metal.

The rapid accumulation of gas beneath the skin of these patients suggests that a chemical may have been the responsible agent. The studies previously mentioned have demonstrated that the rapidity with which gas appears beneath the skin subsequent to injections of powdered magnesium varies a great deal, depending on the species of animal used in the experiment.¹ In rats, for example, this phenomenon occurs more readily than in guinea pigs. Schulz and Walter in their experiments noted the appearance of gas bubbles fifteen minutes after the subcutaneous injection of powdered magnesium. It is questionable whether any known bacterial agent, acting independently, would have been capable of producing local reactions with such rapidity.

Although gas gangrene had been suspected in each of the 3 cases, subsequent study eliminated this diagnosis. The injury which precipitated the syndrome in all 3 patients did not produce extensive laceration or damage to muscle tissue. It is well known that gas gangrene usually develops in a deep, punctured or lacerated wound which extends into muscle and carries with it such foreign bodies as clothing, powder or debris. The constitutional reaction, which is usually severe in gas bacillus infection, was insignificant in these cases. One patient (M. S.) had a normal temperature on admission in spite of involvement of almost the entire arm. The course remained afebrile until the second postoperative day, when several of his wounds became septic. Similarly, a prolonged elevation of temperature was not shown by either of the other 2 cases.

The syndrome discussed in this paper may also be confused with hemolytic streptococcal gangrene described by Meleney.⁵ In this condition too a superficial injury is usually the precipitating factor and subcutaneous tissues are involved in the pathologic picture. However, tumor masses and crepitation do not occur and the rate of spread from the point of injury is less rapid than was observed in these cases. Blisters and bullae develop late in the course of hemolytic streptococcal gangrene.

The bacteriologic studies did not reveal an organism common to all 3 patients. Similarly, cultures of cutting oils and other materials revealed several organisms apparently unrelated to the etiology of this syndrome. Further studies are being carried on with these bacteria.

5. Meleney, F. L.: A Differential Diagnosis Between Certain Types of Infectious Gangrene of the Skin, Surg., Gynec. & Obst. 56: 847-865 (May) 1933.

It may be postulated that a bacterial agent, acting synergistically with the magnesium alloy, may have been responsible for the syndrome. It has, however, been shown that in animals tumor masses may be produced by the injection of sterile magnesium. Further research will determine whether the pathologic process may be accelerated by the presence of certain bacteria in addition to the magnesium.

Whether or not the powdered magnesium alloy is the etiologic agent, this syndrome must be borne in mind in the differential diagnosis of infection characterized by the presence of gas beneath the skin. It is hoped that this discussion will be helpful in bringing other similar cases to light.

SUMMARY

1. Three cases of a new syndrome characterized by the rapid appearance of subcutaneous gas tumor masses within a few minutes after a superficial laceration of the hand occurred in two plants where an alloy composed of 90 per cent magnesium was being used. Each patient had handled this material in a finely powdered form prior to the occurrence of injury.

2. It is possible that an etiologic relationship of this alloy to the syndrome exists.

3. Because this syndrome may simulate gas gangrene, it is important that its clinical characteristics be borne in mind in order that unnecessary surgical procedures may be avoided.

VESICoureTERAL REFLUX ACCOMPANIED BY RENAL COLIC

LIEUTENANT COLONEL J. J. CORDONNIER

Assistant Professor of Clinical Genitourinary Surgery,
Washington University School of Medicine,
St. Louis, on Leave of Absence

MEDICAL CORPS, ARMY OF THE UNITED STATES

The occurrence of vesicoureteral reflux has been recognized for many years. Importance has been attached to its significance as an etiologic factor in upper urinary tract infection and renal damage secondary to back pressure. Extensive studies were made by Graves and Davidoff¹ in this connection, using rabbits and dogs. Their principal clinical interest was in connection with its relation to upper urinary tract infections. It was not until 1934 that the role of vesicoureteral reflux in the production of renal colic was forcefully brought to attention by Lewis and Carroll,² who presented 30 cases of symptomatic vesicoureteral reflux. All cases described by them were secondary to vesical neck or urethral obstruction, and the symptomatology described was characterized by typical renal colic, occurring usually in the presence of a distended bladder, when the patient attempted to void. Individual cases were presented by several other authors in connection with their article. Little has been written since that time concerning this clinical syndrome, and it is felt that attention should again be directed to this condition, particularly with reference to its occurrence in cases of stones in the lower ureter

after operative manipulation for their removal. That vesicoureteral reflux occurs with considerably more frequency than is ordinarily suspected is emphasized

Fig. 1.—Vesicoureteral reflux in left ureter.

by Aschner,³ who reported its presence in 14 per cent of 202 cases in which cystograms were made.

The value of a cystogram, taken after voiding, in the diagnosis of vesicoureteral reflux is clearly demonstrated

Fig. 2.—Vesicoureteral reflux in right ureter and kidney pelvis.

in 1 of our patients. This procedure was described by Bartrina,⁴ who recommended the use of cystograms taken while the patient was voiding for the demonstra-

tion of reflux. My associates and I have followed his technic with some modification, namely filling the bladder with opaque solution, taking an x-ray, having the patient void and then taking a second film.

The etiologic factors involved in the production of vesicoureteral reflux may be divided into three groups as described by Cace:⁵ (1) produced by (a) mechanical causes obstructing flow at the vesical neck and producing dilatation upward, (b) alterations of the ureteral orifice due to chemical causes, postoperative cicatrices, chronic inflammatory lesions such as tuberculosis, or cancer involving the ureteral orifice; (2) dynamic, produced by nerve lesions involving the cauda equina, and (3) congenital malformations, with special emphasis on obstruction at the vesical neck due to urethral valves. Vermooten and Neuswanger⁶ were able to produce vesicoureteral reflux in dogs by incision of the ureterovesical valve. They observed that actual

dition occurred rarely when normal ureterovesical valves were present. Prather¹⁰ recently described a case following extensive injury to the bladder and posterior

Fig. 3—Same case as figure 2 after voiding. Note increased filling of ureter and pelvis.

dilatation of the upper tract resulted only when there was both an infected urine and a ureteritis.

Hemmingsen⁷ presented 28 cases of various lesions of the genitourinary tract in which x-ray studies had been made with the finding of reflux in 4 cases, 3 with prostatic hypertrophy, 1 with tuberculous cystitis. Verrière⁸ presented 3 cases of vesicoureteral reflux occurring following the accidental injection of caustic solutions into the bladder. Dietel⁹ discussed ureteral reflux in connection with pregnancy, with particular reference to its relation to pyelitis. He was unable to demonstrate its presence in any of 50 cases studied by cystography, and his conclusion was that the con-

severe left renal colic. Ureteral meatotomy was performed by means of a cystoscopic scissors and two days later the calculus was passed. Convalescence was uneventful except that the patient began to complain of severe pain in the left kidney region posteriorly, occurring with a full bladder and immediately relieved by voiding. The bladder showed mild trabeculation, and there was a slight degree of prostatic encroachment at the vesical neck. There was no residual urine. A cystogram was made with 500 cc. of skiodan, and a definite reflux in the lower portion of the left ureter was demonstrated (fig. 1).

A white man aged 29, with a diagnosis of right renal calculi made six months prior to admission, presented a typical renal colic on the right side, and a calculus, 2 by 5 mm. in size, was lodged in the right ureter approximately 1.5 cm. above the ureterovesical junction. Conservative treatment was instituted for a period of over two months, including a ureteral meatotomy performed with a Moore electrotonic, and repeated ureteral dilations. The stone resisted all efforts at removal, and a ureterolithotomy was performed. The location of the stone was such that there was unquestionably some damage to the ureterovesical junction during its removal. Postoperative convalescence was uneventful. About one month after operation the patient began to complain of pain in the right kidney region and right abdomen, anteriorly, coming on near the end of urination. Because of the characteristic location of the pain and the clinical history, vesicoureteral reflux was suspected and a cystogram was made with 300 cc. of 10 per cent skiodan. A film was taken, which presented a complete filling of the ureter and pelvis on the right side (fig. 2). The patient was then instructed to empty his bladder partially, and a second film was made (fig. 3). During this process the typical pain of which he complained was reproduced. It is noteworthy that in the second film there was considerably more filling of the calices and definite dilatation of the ureter with some angulation. This was undoubtedly brought about by transmission of bladder pressure up the ureter during voiding. This phenomenon demonstrates the finding of Graves and Davidoff that, with regurgitation, the bladder pressure is transmitted directly to the kidney pelvis, the two structures being in open communication. Furthermore, the reason for the appearance of symptoms near the end of urination is clearly brought out, because at this point maximum dilatation of the ureter and kidney pelvis was obtained. Four months later the patient was studied again. In the interval there had been a moderate degree of improvement in symptomatology and, although the symptoms were less pronounced, there was still some pain in the kidney region at the end of urination. The bladder was filled with 550 cc. of 10 per cent skiodan and an x-ray made (fig. 4). Only a few small shadows in the region of the minor calices of the kidney appeared. There was no filling of the ureter or kidney pelvis. The patient was then instructed to void, and a second film was made after the bladder was almost empty (fig. 5). At this time complete filling of the ureter and pelvis was present. This series presents clearly the value of cystograms taken after voiding in the demonstration of this condition and shows that its presence may be overlooked by using a routine cystogram alone.

CONCLUSIONS

Vesicoureteral reflux occurs more frequently than one would suppose and does produce definite kidney colic in some instances. Its presence should always be suspected in cases of renal colic, particularly in association with obstruction at the vesical neck when no stone is demonstrated.

Operative manipulation on the lower ureter with subsequent damage to the ureterovesical valve is occasionally followed by vesicoureteral reflux.

The employment of a cystogram made after the patient has voided, rather than the use of simple filling of the bladder with a contrast medium, is of definite value in demonstrating this condition.

ARACHNOIDITIS AND PARALYSIS FOLLOWING SPINAL ANESTHESIA

FOSTER KENNEDY, M.D., F.R.S. (EDIN.)

HAROLD M. SOMBERG, M.D.

AND

BERNARD R. GOLDBERG, M.D.
NEW YORK

The literature has many reports of sequelae involving the nervous system after spinal anesthesia. These have been disturbances in sensation, stiff neck, cranial nerve involvement (second, third, fourth, sixth, seventh, eighth and twelfth), impaired bladder and rectal function, hemiplegia and paraplegia, pyramidal tract degeneration, meningoencephalitis, polioencephalitis, myelitis, myelopathy, radiculitis, severe "neuritis," septic and aseptic meningitis, arachnoiditis, cauda equina neuritis and others.¹

Falk² reported headache and stiff neck lasting several days in about 6 per cent of persons after spinal anesthesia. This he regarded not as a complication but as a normal result of spinal anesthesia. More seriously, meningitis has been often reported after spinal anesthesia.³ In 8 cases of so-called aseptic meningitis there were three deaths; the others were "benign" and recovered. In that series, symptoms began sixty hours after the anesthetic had entered the subarachnoid space. There was an increase of lymphocytes in the spinal fluid which disappeared slowly; such a pathologic picture is quite different from the chronic progressive fibrinous arachnoiditis to be reported now. Hammes⁴ described 8 cases with neurologic signs following spinal anesthesia; of these 2 were labeled "chronic arachnoiditis." This diagnosis was a clinical impression supplemented in one case by iodized oil x-ray studies and was not confirmed by operation.

The only verified case of localized arachnoiditis thus far reported was described by Haynes and Smith.⁶ Their patient had signs of cervical cord involvement four days after injection of a pontocaine glucose solution into the lumbar subarachnoid space. Two months later a cervical laminectomy was done; adhesions were found between the arachnoid and cervical cord covering the anterior and posterior nerve roots of the second, third and fourth cervical segments. Some of the adhesions were lysed and improvement followed.

Death has followed spinal anesthesia from involvement of the nervous system. Its incidence in three series has been reported as (a) 5 in 120,000 cases,⁷

(b) none in 250,895 cases⁸ and (c) 3 in 4,010 cases.⁹ In the first series the cause of death was meningitis, septic and aseptic. In the last series death was ascribed to "spinal shock." On autopsy such cases have decidedly thickened meninges and clear evidence of myelopathy. Those cases are much more severe than ours: apparently there was a primary involvement of the spinal cord and a secondary morbid process in the meninges.

REPORT OF CASES

CASE 1.—B. R., a woman aged 51, a housewife, admitted to the neurologic service of Bellevue Hospital on May 24, 1944, was in good health until the early part of 1941, when she was found to have a fibromyoma of the uterus. On April 17, 1941 hysterectomy was done under spinal anesthesia. The anesthetic agent was 125 mg. of procaine. The immediate postoperative course was uneventful and she was discharged from the hospital eleven days after the operation. Four days later she noticed numbness and weakness of the lower extremities and difficulty in walking. These symptoms became gradually worse despite massage and "chiropractic treatment." In the early part of 1943 the left foot dragged on walking. There was stiffness of the left leg in January 1944. This grew worse; by March there was added pain in the upper back and shoulder girdle radiating to the hands. The patient then became incontinent of urine and feces.

On admission the general physical status was normal. However, she had slightly irregular pupils, the left larger than the right, spastic paraparesis of the lower extremities, atrophy of the peroneal muscles of both legs without fibrillations, absent abdominal reflexes, overactive knee jerks and occasionally clonus. The Babinski sign was positive on both sides. Sensory examination revealed diminution to pin prick below the first lumbar spinal segment, more pronounced on the right, diminution to hot and cold sensation below the second lumbar segment, impaired vibration sense below the third lumbar segment and impaired position sense in the toes. The perianal zone was spared. A lumbar puncture was done; the initial pressure was 120 mm. of spinal fluid. Jugular compression produced a slow rise in pressure; when the pressure was released the spinal fluid level fell slowly, indicating a partial block. The fluid contained 90 mg. of protein per hundred cubic centimeters of fluid and 3 lymphocytes per cubic millimeter. The Wassermann reaction was negative and the colloidal gold curve flat.

A preoperative diagnosis of "arachnoiditis secondary to spinal anesthesia" was made. Laminectomy was done on June 27, 1944: an obstructive arachnoiditis around the twelfth thoracic spinal segment was found. A soft rubber catheter was used to break up the adhesions and relieve the block. After operation the patient had a low grade fever for eight days. There was gradual improvement in her symptoms and she was able to void spontaneously on the eighteenth postoperative day. During the remaining twelve days of her hospitalization the patient received baking and massage.

A letter from the patient dated Sept. 25, 1944 states that she "can move her legs much more freely and can stand on her feet for a few minutes at a time."

This case history demonstrates two features: 1. The symptoms did not occur after operation until the patient had left the hospital; since she had completely recovered from the hysterectomy, she failed to correlate her paralytic complaints with any preceding surgical procedure. 2. The surgeon and the anesthetist were never informed by the patient of the postoperative complication.

CASE 2.—J. M., a man aged 50, a lithographer, admitted to the neurologic service of Bellevue Hospital on July 25, 1943, had been in good health until April 8, 1943, when a bilateral inguinal herniorrhaphy was done under spinal anesthesia. The

anesthetic agent was 10 cc. of eucupine with procaine. There were no immediate postoperative complications and the patient was discharged from the hospital twenty-one days after operation. A few days later he complained of weakness of the lower extremities and of a dull pain in the low back area, radiating to both buttocks. These pains became progressively worse; in a few days more he noted pins and needles sensation in his feet. His condition deteriorated so that a week before coming to Bellevue Hospital he could not walk without support and passed urine with difficulty.

The general physical status was normal except for carious teeth, bilateral herniorrhaphy scars and weakness of the rectal sphincter tone. However, both legs were very weak, especially the peroneal muscles; there was foot and toe drop on both sides. The upper abdominal reflexes were depressed, the lowers absent. The knee and ankle jerks were more active on the right. The Babinski sign was present on the right and was equivocal on the left. There was unsustained ankle clonus on the right. Sensory examination revealed diminished appreciation of pain and temperature below the first lumbar spinal segment. Vibration sense was impaired at the hip and absent below the knees. Position sense was lost in the right foot and impaired in the left. The sacral area was spared. Several attempts at lumbar puncture failed to produce any spinal fluid. The blood Wassermann reaction was negative; blood count and urine were normal. X-ray examination showed no abnormality of the lumbar spine.

A preoperative diagnosis was made of "adhesive arachnoiditis secondary to spinal anesthesia." Laminectomy on Aug. 5, 1943 revealed adhesions completely encircling the conus medullaris. The nerve roots of the cauda equina were enmeshed by these fibrous bands. Lysis was performed wherever possible and free flow of spinal fluid established below the site of the adhesions. After operation the patient had many episodes of cystitis; these were controlled by Munro tidal drainage. Four months later the chronically ill patient was transferred to the Goldwater Memorial Hospital for further care. A report on Sept. 10, 1944 states that he has had some slight return of function in the lower extremities; he is still greatly disabled.

This case resembles the first in that symptoms did not occur till the patient had left the hospital. The anesthetist and the surgeon were alike unaware that their patient was suffering from severe sequelae of the spinal anesthesia, which they had recorded as being without complication.

CASE 3.—T. B., a man aged 29, a practical nurse, admitted to the neurologic service of Bellevue Hospital on Jan. 11, 1944, had been well till May 3, 1943, when he complained of sharp abdominal pain and was taken to the Jersey City Medical Center; there a diagnosis of acute appendicitis was made. Appendectomy was done under general anesthesia. The postoperative course was stormy; a septic type of fever frequently reached 104 F. Twenty-three days after operation the patient left the hospital against advice and was admitted to the Hospital of the United States Maritime Service Training Station at Sheepshead Bay. There he continued to have high fever; he complained of severe abdominal pain. A gastric x-ray examination revealed the appearances of a perforating ulcer.

On June 3, 1943 an exploratory laparotomy for a suspected perforating gastric ulcer was done under continuous spinal anesthesia. The anesthetic agent was metycaïne; 2 cc. of a 10 per cent solution was diluted to 10 cc. with spinal fluid and given in fractional doses. Anesthesia was satisfactory except that at one time the patient complained of difficulty in breathing. An intratracheal tube was inserted and oxygen administered. Later, when the spinal needle was dislodged, the anesthesia was supplemented with cyclopropane and ether. Following operation, the patient's condition was good. On the fifth day fever recurred and he was unable to pass urine. Further, there was found paralysis of both lower extremities. The signs of spinal cord involvement spread upward to include the clavicular level and both upper extremities.

Three weeks after the operation the patient was completely paralyzed in the lower extremities and at times complained

8. Babcock, M. E.: Spinal Anesthetic Deaths: A Survey, *Anesth. & Analg.* 11: 184-188 (July-Aug.) 1932.

9. Lyford, J.; Berger, O., and Schumacher, H. B.: An Analysis of Deaths in the Operating Rooms of the Johns Hopkins Hospital, with Special Reference to Those Occurring Under General and Spinal Anesthesia, *Bull. Johns Hopkins Hosp.* 70: 488-503 (June) 1942.

of pains and tingling sensations in the arms and fingers. Within several weeks he began to regain some motion of the lower extremities so that he could walk with help. On discharge from the Maritime Service Hospital the patient was described as having a typical ataxic gait, without reflexes in the lower extremities.

On Dec. 17, 1943 he suffered burns of both knees as he leaned against a radiator. There was anesthesia of the lower extremities, and he lacked any appreciation of temperature. The burns were dressed in the emergency ward of Bellevue Hospital and subsequently elsewhere. The right knee became reddened and swollen; a week later the patient had stiffness of the neck and face and much difficulty in swallowing. On Dec. 24, 1943 he was admitted to Bellevue Hospital; here he was found to have tetanus. He received 420,000 units of tetanus antitoxin. Improvement was rapid and progressive. On Jan. 10, 1944 he was transferred to the neurologic service for study.

He was a well made man. General physical examination was negative except for the scars of burns and operations. There was a flaccid paralysis of both lower extremities. There was thinning of the hands attributed to disuse, as strength of the arms and grip was good. The deep tendon reflexes of the upper extremities were equally active; the upper abdominal reflexes were present, the lowers absent; the knee and ankle jerks were absent bilaterally. The Babinski sign was present on both sides. There was a loss of all forms of sensation below the ninth thoracic spinal segment. Coordination in the arm movements was good. The blood Wassermann reaction was negative; the urine and blood count were normal. Several attempts at lumbar puncture were made, but no fluid was obtained. On January 15 laminectomy from the fourth to the tenth thoracic spinal segments was carried out under general anesthesia. The dura was tightly adherent to the arachnoid and spinal cord; there was no free flow of spinal fluid. At the seventh thoracic segment a small calcified plaque was found in the arachnoid. Above the plaque a cystic tumor-like swelling of the cord was found, covered by tortuous veins. The dorsal columns were separated by blunt dissection but no cyst was encountered.

After operation there were paresthesias of the thighs and legs, and the sensory loss level receded from the ninth thoracic to the first lumbar segment. Motion of the legs improved. The postoperative course was complicated by a cystitis and epididymitis. He was given radiation therapy and was to have had a hip brace, but before it could be fitted he left against advice on the fifty-eighth postoperative day. At present the patient is at the United States Marine Hospital on Staten Island. His condition is unimproved.

Perhaps a postscript might be written here regarding a patient seen by one of us in private practice, referred by two of the best known medical men in the country as "neurotic":

Mrs. J. B., aged 49, complained of "shooting and tying up pains" around the body from below the breast to below the navel.

A hysterectomy had been performed three and one-half years before under spinal anesthesia. When the injection had been made, the arms and hands and legs went "numb and paralyzed," "the legs at once, the arms a few minutes later." She then began choking and stopped breathing. A pulmotor was used; she was brought back from the operating room to her bedroom and remained flat on her back for twelve hours. The arms and legs recovered power in about two hours, but "they all felt like chilblains for about ten hours longer." A new symptom appeared later, at which time "the left arm felt lame; there was pain in the forearm which occupied also the left inner fingers."

After hysterectomy she gained 50 pounds (23 Kg.) weight in five months and at the time of examination weighed 186 pounds (84 Kg.) in her underclothes. There was found severe hyperesthesia on the level of the fourth dorsal to the tenth dorsal segments on both front and back. She described the skin in this area as feeling "scalded." Her clothes were a great source of irritation.

The left knee jerk and left ankle jerk were present sharply without reinforcement. The right knee jerk and right ankle jerk were absent on reinforcement. In addition, she proved to have a bursitis over the head of the left radius.

The presence of deep reflexes on one side and their complete absence on the other was clear evidence of spinal cord morbidity, as was the radicular pain around her body in the same area in which there was a "scalding" increase of normal skin sensation.

COMMENT

Experimental and clinical studies have tried to determine the causes of neural symptoms after spinal anesthesia. Some of these are (1) technic, particularly in the lumbar puncture;¹⁰ (2) infection;⁷ (3) the chemotoxic effect of the anesthetic agent. Septic and aseptic meningitis¹¹ and even death¹² have been reported following diagnostic lumbar puncture, but complications after spinal anesthesia differ in kind and strength. So the introduction of a needle into the lumbar subarachnoid space would not seem to be the injurious factor in spinal anesthesia. Lundy,¹³ by a series of well controlled experiments on dogs, has made this clear.

Infection by an unknown organism has been insinuated by some investigators.⁷ This, they thought, might explain the "incubation" period prior to the onset of symptoms following spinal anesthesia. Of course, this might be possible. In one series¹¹ in which 11 of 96 patients operated on under spinal anesthesia developed septic meningitis, frank infection was the underlying factor.

The evidence for a chemotoxic effect of the anesthesia is ample. The investigations of Spielmeyer¹⁵ and Wassidlo¹⁶ as early as 1908 and Davis¹⁷ more recently have shown that in experimental animals the commonly used spinal anesthetic agents, when injected into the spinal subarachnoid space, produced (1) constant but varying degrees of leptomeningitis, (2) passive congestion of the ganglion cells of the gray matter, (3) swelling and fragmentation of the axis cylinders and (4) degenerative changes in the fiber tracts of the spinal cord. Burford,¹⁸ in his study on human tolerance for procaine, says that there is a tendency of the anesthetic agent to affinity for the immediately adjacent elements at the cord surface and within the cord structure itself. This gives rise to a picture like combined tract degeneration. Oddly enough, the leptomeningeal reaction stressed by Davis is not described by Burford.

Preexisting disease of the central nervous system has been shown to be a definite contraindication to spinal anesthesia.⁶ It is felt that the chemotoxic effect of the anesthetic agent aggravates the pathologic process; there is therefore need of careful neurologic examination of every patient before spinal anesthesia. feels that individual sensitivity may be needed to produce these reactions to spinal anesthesia, as few patients have central nervous system complications. Of course, such theorizing may well be the explanation for every pathologic process.

Hyslop,²⁰ in discussing Brock's paper, mentions 0.5 per cent as the incidence of complications after spinal anesthesia in his experience but adds that many men writing on spinal anesthesia have been ignorant of, and have therefore omitted, reference to sequelae that have occurred. This has been our experience.

SUMMARY

1. Three verified cases of spinal arachnoiditis and paralysis following spinal anesthesia were encountered.
2. Many surgeons and anesthetists are unaware that these sequelae exist because they appear after the patient has been discharged by the surgeon.
3. The gravity of possible spinal arachnoiditis and subsequent paralysis must enter into the meditations of surgeons and anesthetists when determining procedure.

THE EFFECT OF VIVAX MALARIA ON SPINAL FLUID AND BLOOD SEROLOGIC TEST FOR SYPHILIS

MAJOR HARRY M. ROBINSON JR.

AND

MAJOR WILLIAM W. McKINNEY

MEDICAL CORPS, ARMY OF THE UNITED STATES

It has been known for many years that infectious diseases such as malaria, yaws, upper respiratory infections and leprosy are productive of biologic false positive serologic tests for syphilis. It is our purpose in this study to determine the effect of vivax malaria on the spinal fluid and blood serologic reactions. Various investigators have reported on the incidence of false positive reactions in the blood of malarial patients. Fellows¹ stated that in 3,244 cases there was an incidence of 9.9 per cent positive serologic tests for syphilis but in only 3.1 per cent were malarial parasites demonstrated, and when parasites were discovered there was a disagreement between the first and second blood tests in 64.8 per cent of the cases. Burney, Mays and Iskiant,² working with inoculated malaria in non-syphilitic patients, found that all cases gave a false positive serologic test for syphilis at some time during the fever therapy.

CASES STUDIED

These studies were carried out on a group of soldiers who had been in a malarious district for several months and had been transferred to a nonmalarious district three months prior to the beginning of this investigation. One hundred nonsyphilitic white male patients with vivax malaria, proved by finding *Plasmodium vivax* in smears of the peripheral blood, were studied. The range in age was from 20 to 35 years, the mean age being 26.5. All patients except for malaria and its side

effects were healthy. Nine of the patients examined were having their initial attack of malaria, but the remainder had been previously hospitalized with proved cases of malaria for from one to sixteen times (table 1). From this table it will be noted that in the greatest number of cases studied there were from one to four attacks

prior to the one on which this study was made. All patients were put on atabrine therapy as soon as the malarial parasite was discovered in their blood smears.

METHOD OF STUDY

The patients were arbitrarily selected for this study, the only requisite being a positive blood smear for malarial parasites associated with a clinical attack. Lumbar puncture was performed and blood was taken for serologic tests from all patients within five days after the diagnosis of malaria was made. If the blood test was positive or doubtful, the patient was bled at weekly intervals thereafter until a negative test was obtained. The standard three tube Kahn flocculation test was performed on all blood specimens submitted and the spinal fluid was tested with the standard Kahn test, Pandy and cell count.

RESULTS

The spinal fluid Kahn reaction was negative in all cases tested. In 2 cases the Pandy was reported as "a trace." The cell count was within normal limits in all specimens.

The blood serologic test for syphilis was reported as positive in 33 cases, doubtful in 11 and negative in 56; therefore 44 per cent of the cases examined revealed

2. Burney, L. E.; Mays, J. R. S., and Iskiant, A. P.: Results of Serologic Tests for Syphilis in Nonsyphilitic Persons Inoculated with Malaria. Am. J. Pub. Health 32:39 (Jan.) 1942.

some change in the blood Kahn reaction (table 2). The patients with negative blood reactions were not followed after discharge from the hospital. Two of the patients with positive reactions were lost from observation. Twenty-six (83.8 per cent) of the remaining cases giving positive Kahn reactions became negative after four weeks and all had become negative after ten weeks. Of the 44 patients in whom there was some change in the serologic test for syphilis, 75 per cent had negative reactions after four weeks and only 10.3 per cent still showed some change at the end of six weeks, as shown in the chart.

SUMMARY

Blood serologic tests and spinal fluid examinations were made on 100 nonsyphilitic white men with proved vivax malaria. Weekly examinations of the blood were done on all patients with a reported positive or doubtful Kahn reaction until a negative reaction was obtained.

Change in reaction. Solid line, patients with positive reactions, broken line, patients with doubtful reactions

CONCLUSIONS

1. Vivax malaria did not produce any change in the spinal fluid Kahn reaction in any of the 100 patients in this series.
2. No elevation of the spinal fluid cell count was noted in any specimen.
3. In 2 instances the Pandy reaction was reported as "a trace."
4. Thirty-three per cent of the cases examined gave positive blood Kahn reactions and 11 per cent gave doubtful reactions.
5. There is no apparent correlation between the number of attacks of vivax malaria and the development of positive serologic reactions for syphilis.
6. Eighty-three and eight-tenths per cent of those with positive reactions had negative reactions at the end of four weeks.
7. Seventy per cent of those with doubtful reactions had negative reactions at the end of four weeks.
8. The serologic reaction for syphilis was negative in all cases at the end of eleven weeks.

TRAUMATIC VASOSPASTIC DISEASE OF THE HAND (WHITE FINGERS)

WITH PARTICULAR REFERENCE TO BIOPSY FINDINGS

E. S. GURDJIAN, M.D.

AND

L. W. WALKER, M.D.
DETROIT

It has been known for some time that workers exposed to repeated percussion may develop circulatory disturbances in the hands. The condition is most frequently associated with the use of the pneumatic hammer (or jack hammer) and consequently the term "pneumatic hammer disease" is the one most commonly employed. Other synonyms are dead fingers, white fingers, traumatic vasospastic syndrome, vasospastic disease of the hands and Raynaud's phenomenon. The industries in which pneumatic tools are now employed are numerous and increasing. These industries include mining, quarrying, road making, shipbuilding, locomotive and other work shops, airplane construction and shoemaking. The tools employed are pneumatic hammers, chisels, riveters, road drills and pounding and lasting machines. The condition has also been said to occur in telephone operators.

Other conditions associated with the use of vibrating tools have been described, but they are not within the scope of this paper. These conditions include changes in muscles, bones and joints, and nerve disturbances.¹

The first report on pneumatic hammer disease was by Loriga of Rome in 1911,² while the first report of the disease in this country was made by Cottingham in 1917.³ His investigation was made at the request of the Journeymen Stone Cutters' Association on men using the pneumatic chisel in the Indiana limestone belt. At this time there was much agitation against the use of the pneumatic chisel. The United States Bureau of Labor Statistics and the United States Public Health Service intervened in the dispute. Dr. Alice Hamilton was sent to Indiana to study the problem. Her report was published in 1918.⁴ From that time on sporadic reports have appeared in the literature, but none have described the clinical findings more thoroughly or completely.

The clinical pattern of traumatic vasospastic disease of the hands is almost stereotyped. After a few months to several years of exposure to the vibrations, the patient notices attacks of blanching and numbness of the fingers. The pallor is much more pronounced than in Raynaud's syncope, but it is not succeeded by the stage of extreme asphyxia so characteristic of the former. It is not symmetrical even when in both hands. In right-handed persons the little, ring, middle and more rarely the index finger of the left hand and the tips of the fingers of the right hand are usually involved. It is more common in the left than in the right hand, because the tool is held in the left hand with the cutting

edge pressed against the object. The handle of the hammer is held in the right hand. In left-handed men the condition in the two hands is reversed.

The attacks may occur while the patient is working. Usually the blanching is most pronounced early in the morning, particularly in cold weather. The attacks can be brought on by washing the hands in cold water or going outdoors for a while in cold weather. They usually come on more frequently in the winter months, when exposure to the cold is more prone to occur. Emotion does not appear to produce the attacks. Some workers have complained that if they hold their hands up for a few minutes the affected fingers grow numb. Rothstein⁵ examined 8 employees using the air hammer and found a decrease in sensation of touch, pain and temperature over the affected fingers. In none of the men was this decrease of severe degree. In addition to the blanching and numbness, most patients complain of a discomfort in the hands during the attacks and for a few minutes following the attacks. In a few instances this discomfort is described as a "toothache-like" pain.

The attacks do not result in the wasting and death of tissue. The disease is not attended by the thickening of the skin as in the scleroderma which may accompany Raynaud's disease. One case of diffuse scleroderma involving the face and hands and Raynaud's phenomenon is described as developing together in a pneumatic tool worker.⁶ The dorsalis pedis and the posterior tibial pulsations could not be felt. The author admits that "the vibrations may not have caused the scleroderma." Junghanns⁷ describes a case of gangrene of the finger tips of the left hand in a worker who had used the air hammer for eleven years. Nodules later developed in both forearms. Microscopic studies of the blood vessels in these nodules revealed lesions similar to those found in Buerger's disease.

The disease is limited to the hands, although between attacks some workers have complained of numbness involving one half of the body.⁴ A case of unilateral peripheral vascular disease occurring in the left foot in a worker using this foot to operate a pneumatic drill press has been described.⁸ Gangrene of the foot developed, and the leg was amputated. Microscopic examination of the blood vessels revealed Buerger's disease.

In a study of 67 cases of white fingers in workers using the air hammer⁴ the length of experience with the machine ranged from one and a half to sixteen years. The average time among those who were affected was 5.7 years. The average among the employees who reported that they had not been affected injuriously was 9.2 years.

Rieder⁹ studied 250 workers who had used the air hammer up to forty years. Of these only 75 were entirely free of symptoms. Eighty-six had white fingers. Hamilton⁴ found among 38 limestone cutters that there were only 4 who had never had white fingers. Out of 50 granite workers who had used the air hammer only 7 had escaped having the disorder.

When the workers stop using the pneumatic hammer, the symptoms usually improve slightly but do not disappear. According to Anderson¹⁰ the disease may be relieved on change of occupation if it has not become chronic. Wright¹¹ states that rest from the regular occupation results in improvement only if the condition is early and mild. The prognosis as to complete recovery is doubtful and usually poor, although a few instances of spontaneous recovery have been reported.⁴ Men who have given up the use of the air hammer for many years still have vasospasm of the affected fingers in cold weather.

The present study is concerned with the clinical findings and the microscopic findings in the capillaries and arterioles of the fingers in 6 women war workers using a pneumatic riveter in airplane construction work in Detroit. To our knowledge this is the first time that the condition has been described in women and the first time that microscopic studies of the finger tips have been done.

TABLE 1.—Observations in Six Cases

Case	Age	Sex	Time of Onset	Biopsy and Time After Onset	Extent of Involvement
1	25	♀	2 mo.	Yes/15 mo.	Index, long, ring and little fingers, left hand
2	23	♀	11 mo	Yes/17 mo.	All fingers and tip of thumb, left hand
3	22	♀	11 mo.	Yes/20 mo.	All fingers and tip of thumb, left hand
4	20	♀	10 mo.	Yes/11 mo.	Index, long, ring and little fingers, left hand
5	26	♀	11 mo.	Yes/ 7 mo.	Index, long and ring fingers, left hand
6	34	♀	2½ mo.	Not done	All fingers and tip of thumb, left hand; lateral three toes, left foot; one or more toes, right foot

⁴Typically the fingers and the tip of the thumb of the left hand are involved. Patient 6 has the typical hand involvement but also has had vasospasm of one or more toes of both feet. It is difficult to explain the lower limb vasospasm on the basis of the use of the pneumatic hammer alone, since the right hand has escaped involvement. Possibly a vasospastic diathesis may be a factor in her case. Unfortunately, no biopsy was permitted.

CASE HISTORIES

The age, sex, time of onset, time of biopsy and extent of involvement of the 6 patients are given in table 1. All patients are right handed. Since the clinical picture is almost the same in all cases with the possible exception of case 6, the description of the attacks, the progress, the temperature readings and the biopsy findings will be considered together.

Description of Attacks.—On response to cold air, particularly in the morning, attacks of vasospasm were initiated. During the spell, the involved fingers became white (fig. 1), anesthetic and painful. When the patient entered a warm place the fingers changed to bluish yellow and then to pinkish, and soon the vasospasm was followed by vasodilatation. During recovery from the attack there was a feeling of "pins and needles" and pain, described by some as a "toothache-like pain." In between spells the hands were normal. At times there would be no attacks for many days, even in cold weather. One of the patients developed vasospasm of the affected fingers in summer while holding a cold bottle of carbonated beverage. The spells were not all of equal severity; in different attacks one or more phalanges of one or more fingers were involved. In table 1 is given the maximum extent of vasospasm up to the time of the writing of this paper.

11. Wright, Irving: Industrial Medicine and Its Relation to Peripheral Vascular Disease and Injury, Indust. Med. 9: 463, 1940.

Neurostatus.—The texture of the skin and nails was normal in every case and the hands were moist. There was no localized atrophy in the hands. Tendon reflexes were normal. There were no sensory changes except in case 6, in which slight hypesthesia of the left index finger existed from the metacarpophalangeal joint down.

Fig. 1.—Vasospasm produced by exposure to a temperature of 35 F. (hospital refrigerator). This photograph was obtained in May 1945, the outside temperature being in the high forties. The simultaneous cooling of the body and the affected fingers is more successful in producing the vasospastic attack. When the patient left the refrigerator the fingers turned to a cherry-red in a matter of a few minutes. Note that the general appearance and contour of the skin and nails of the hand are normal.

Progress.—For the first few months following the onset of the condition only the tips of the fingers were involved. Within three to four months the vasospastic condition extended to the metacarpophalangeal joints, and in 3 cases the tip of the thumb also was affected. In case 6 the lateral three toes of the left and the second toe of the right foot underwent vasospastic spells. Although fourteen months or longer have elapsed since the patients stopped using the pneumatic hammer, the attacks of vasospasm still continue. However, all are employed and this condition has not been disabling. In conclusion, it may be said that there is some progress in the extent of involvement for the first three to four months following the onset. Thereafter the condition usually remains stationary. Three patients have complained of dull ache on exertion in the left upper limb between attacks of vasospasm.

Temperature Studies.—Temperature readings of the fingers, the toes and the upper and lower limbs were obtained on one or more occasions. Readings were taken after the patients were first exposed to a room temperature of 20 C. (68 F.) for a half hour. Later they were exposed to a room temperature of 30 C. (86 F.) for one hour and their temperatures studied. The vasomotor response was normal. The typical readings are given (table 2).

Biopsy and Pathologic Findings.—Five of the 6 patients consented to a biopsy of the finger tips. Three were obtained from the tip of the long finger and two from the tip of the ring finger of the left hand. Block procaine hydrochloride anesthesia was used. About 15 cc. of a 2 per cent solution was injected along the metacarpophalangeal articulation. The finger tip became completely anesthetized with no change in its texture from the local anesthesia. A median incision was made on the palmar surface of the last phalanx and a slice of tissue $\frac{3}{4}$ inch long and $\frac{1}{8}$ inch wide was removed. This included the skin and the underlying connective tissue bed. The wound was approximated with two interrupted silk sutures, and healing was entirely normal in each instance.

The tissue was fixed in solution of formaldehyde and embedded in paraffin. Serial sections were made, and the tissue was stained with hematoxylin eosin. Autopsy material was obtained in the same manner and was used for control. The sections were studied carefully for changes in the capillaries, arterioles and veins. The

capillaries appeared normal except in two sections, in which a red staining amorphous substance was noted within the capillary. Since similar changes were noted in the autopsy material, this was not considered abnormal. The larger vessels had a normal adventitial layer, the muscular coat appeared normal and the endothelial

Fig. 2.—Pneumatic hammer used by our patients

lining showed no pathologic changes in all sections studied. There were no evidences of endothelial proliferation or occlusive phenomena. There was no evidence of inflammatory reaction in any of the sections studied.

COMMENT

The pneumatic hammer used by the patients weighed 3 pounds. The riveting surface was $\frac{1}{4}$ inch in diameter and the expended pressure was 17½ pounds. The

machine struck between 3,000 and 3,400 times per minute, the most efficient rate according to the engineers. A photograph of the pneumatic hammer is shown in figure 2. The riveted object was held in place with the left hand, the latter receiving most of the imparted vibrations. The operator worked eight and three-quarter hours per day. The maximum period of continued work without rest was in the neighborhood of two hours and fifteen minutes. In the 6 cases observed, the shortest interval of time before the condition appeared was two and a half months, while the longest period was eleven months after the use of the pneumatic machine. It is interesting to note that all the employees operating this particular machine sooner or later developed vasospastic disease of the left hand.

Since these patients have come under observation, a new stationary pneumatic hammer has been perfected which does not necessitate the handling of any tools. All the operator has to do is to place the part to be riveted into the machine. By this procedure he is exposed to almost no vibrations. This stationary riveter is about four times more efficient than the one operated by hand.

The study of the cases described reveals that the encountered vasospastic disease is unilateral and in the left hand in each instance. The little finger has escaped involvement in only 1 patient. The thumb was normal in the beginning in all cases, but with the progress of the disease there was minimal involvement in 3. In 1 there was vasospasm of the lateral three toes of the left and the second toe of the right foot.

Although the patients have not used the pneumatic hammer for more than a year, attacks of vasospasm still continue. In no instance has there been evidence of bilateral involvement such as in Raynaud's disease. The texture of the hand and skin has remained normal. There have been no instances of scleroderma and no evidence of increasing lack of proper circulation to the finger tip as seen in the later stages of Raynaud's and in Buerger's disease. The condition appears to be a vasospastic disease of the fingers without organic changes in the tissues. Most of the patients have been observed for almost two years, and during this period there has been no appreciable increase in the severity of the condition after the first few months.

In these cases the vasospasm lasts for a short time, frequently disappearing a few minutes after the patients enter a warm building. During the attack there is anesthesia of the affected fingers, and the limb is painful. During the period of recovery most patients complain of a feeling of "pins and needles" and pain for several minutes. The color of the affected parts changes from a cadaveric white to a cherry-red and then to normal within a matter of minutes.

A study of the temperature ranges of the upper limbs revealed satisfactory vasomotor response, which is different from the condition seen in late Raynaud's disease or in Buerger's disease.

The microscopic study of the fingers showed no change in the structure of capillaries and arterioles. It is admitted that since we have only hematoxylin eosin preparations at our disposal, minute changes in cell structure may have been missed. However, gross occlusive phenomena, proliferating intimal changes and inflammatory reaction were not seen. In this respect the condition is similar to the findings in early Raynaud's disease but unlike the findings in Buerger's disease.

The mechanism of the production of this disorder is difficult to explain. Hamilton⁴ considered the low temperature of the workshop as being significant in her study of stone cutters. In our cases the operators worked in room temperatures of 72 to 78 F., so that the importance of low temperatures in the production of the disease is to be discounted.

Although low temperatures are not necessary to cause the disease, they do initiate the attacks once the condition has been established. In the study of our material we have repeatedly noted that cooling of the entire body helps to cause the vasospasm rather than the mere local cooling of the affected hand.

The other factor pointed out by Hamilton⁴ was the anemia of the hand from holding the pneumatic hammer too tightly. This may be important.

The third possibility is injury to myoneural junctions of arterioles in the fingers, disturbing fine mechanisms of chemical adjustment, with resultant loss of vasomotor control. In the study of our cases we have been repeatedly impressed by the fact that in the diseased fingers exposure to cold causes more than a normal response resulting in vasospasm and on warming the fingers there is again more than a normal response, resulting in capillary dilatation characterized by a cherry-red color of the affected parts.

The development of the condition in our cases in a relatively short time (average six to eight months) may be due to the fact that primary vasospastic disease of the extremities is more common in the female. In Hamilton's study an average of one and one-half to five years elapsed between the beginning of the use of the pneumatic hammer and the appearance of the disease.

Our patients have not received special forms of treatment such as sympathetic block or sympathectomy, because such treatment was refused and also because their handicap did not seem to warrant radical means of therapy. It is hoped that in the near future we may be able to study the effect of thoracic sympathectomy on the course of this disease in some cases. From time to time diathermy and heat treatments and iontophoresis with mecholyl have been employed with no appreciable change in their condition. In this connection it may be pointed out again that some patients with traumatic vasospastic disease have worked for as long as twenty years following the onset of the condition with no appreciable increase in the severity of the symptoms. Others have gone into other occupations and have had recurring attacks of vasospasm in the affected limb for as long as sixteen years after the discontinuance of the use of the pneumatic hammer.⁴

From the study of our cases and of the cases described in the literature certain factors in the prevention of this disorder are evident. If the object to be riveted or hammered is held in one hand and the hammer is operated with the other hand, the hand holding the object will be affected. Therefore, mechanical devices to hold the object are most desirable. Other mechanical devices for holding the tool of the hammer, instead of by hand, would prevent the development of the disorder in the hand used to guide and steady the tool. This is important in stonecutting and allied occupations. Other factors which may be important in the prevention of the disorder or further development of the disease are adequate periods of rest from the use of the hammer and early recognition of the disorder and immediate discontinuance of the use of the hammer in these cases.

CONCLUSIONS

1. In 6 cases of traumatic vasospastic disease of the hand no demonstrable organic change in the capillaries and arterioles of the finger tip has been demonstrated in biopsy studies. In this respect the condition is similar to the pregangrenous stage of Raynaud's disease.

2. The appearance of the disease in much shorter time than has been reported in the literature in male patients, and also because all patients thus employed developed the condition, suggests that traumatic vasospastic disease may be more prevalent in the female than in the male.

3. The clinical course of our patients is characterized by attacks of benign vasospasm with little increase in severity over a period of two and a half years' study. However, the discontinuance of the use of the pneumatic hammer has not resulted in a single case of relief.

4. The manner of operation of the pneumatic hammer is important in the prevention of this disorder.

ABSTRACT OF DISCUSSION

DR. GEZA DE TAKATS, Chicago: When the delicate neurovascular mechanism of the human hand is subjected to a vibration rate of 3,000 or more a minute a group of phenomena may occur which roughly fall into two patterns. The authors' excellent description of the digital vasospasm initiated by cold, producing no structural changes and lasting for many years, requires no further discussion. The fact that histologic changes in the blood vessels were absent is very significant, since the primary lesion seems to be elsewhere. During the last year I examined another type of patients who had used a small rotary air-driven tool, weighing about 1½ pounds, with a vibration rate of 12,000 revolutions a minute. The amplitude of vibration was one to three thousandths of an inch, and there was considerable exposure to cold air. Such patients, while sensitive to cold and while showing some evidence of capillary stasis, primarily exhibited a peripheral neuritis of ulnar or median distribution. Their hands, which had been alternately splinted or massaged for the relief of pain, showed the glossy skin, the atrophic musculature, the contracted tendons, the stiff joints and the osteoporosis of the causalgic state. The pain was of a burning character, ascending in type, frequently aggravated or confused by superimposed hysterical anesthesia and anxiety neurosis. Whether this type of hand, because of the higher vibration rate, is simply a more advanced form of the vasospastic hand is impossible to state with certainty. It is more than likely that all these vibrating tools produce a percussion neuritis. I have not yet had the courage to obtain a biopsy of a peripheral nerve from such a hand. Everything we know of the causalgic state would indicate that such a biopsy would aggravate the patient's symptoms. However, the study of Denny-Brown's experiments with a single percussion of a nerve trunk (*J. Neurol. & Neurosurg.* 7:76, 1944) indicates that the myelin sheath and the Schwann sheath easily rupture; that the damaged myelin escapes into the endoneurial space and sets up an irritation. Such an internal disorganization of a mixed nerve is the underlying histologic picture of causalgia, with its incoordination of circulation (de Takats, Geza: *Causalgic States in Peace and War*, *THE JOURNAL*, July 7, 1945, p. 699). Repeated sympathetic blocks have been done on these patients and have helped the vasomotor and the pain phenomena. Often, however, the previous splinting has produced intractable contractures. A defiant attitude develops. It is important then to treat such patients with the utmost urgency, since pain will prevent movement and produces protective muscle spasm. The question is raised whether patients with a high vascular tone are more vulnerable to air-hammer disease. This could be worked out with a suitable test (Naide, Meyer: *Am. J. M. Sc.* 207:606 [May] 1944). Clinically a cold, sweaty hand is often seen in such patients. It is not surprising that a patient with severe diabetic neuropathy in other extremities exhibited the most severe air-hammer hand I have seen, since she already had a widespread demyelinating process. There may be other

contributing factors to this percussion neuritis, but one should repeat the authors' excellent suggestion that it should be possible to eliminate this tool entirely. In many ways this type of nerve injury is more difficult to repair, since damaged myelin and the naked axon cylinders poorly insulated from each other set up long-lasting irritative phenomena.

HERNIAS AND SERIOUS INJURIES IN
MARITIME COMMISSION
SHIPYARDS

WITH REFERENCE TO PREPLACEMENT
EXAMINATIONS

CHARLES M. MCGILL, M.D., M.P.H.
Director, Division of Industrial Hygiene, Oregon State
Board of Health
PORTLAND, ORE.

Shipyards working under contracts for the United States Maritime Commission employed, during the war emergency period, about one million persons in yards located on the perimeter of the United States. Soon after the true magnitude of the shipbuilding program became apparent the Maritime Commission and the United States Navy, realizing the need to increase production, adopted a set of "Minimum Requirements for Safety and Industrial Health in Contract Shipyards."¹ These requirements were designed to conserve manpower and promote the physical welfare, health and safety of employees. One of the basic precepts was the mandatory establishment of preplacement physical examination procedures in each of these contract shipyards (par. H-6.1, ref. 1). Consequently all shipyards of the Gulf and East Coast regions and some of those in the Great Lakes region which had not previously required such examinations developed necessary facilities and plans to include them in their employment procedure. Shipyards operating on the West Coast, however, have not complied with the requirement.

The Pacific Coast "Master Labor Agreement" between the American Federation of Labor and the Pacific Coast shipbuilders, section 11, states in part "There shall be no doctor's physical examinations nor age limits, except as required by law." Negotiations to amend this clause have been continued by the contractors, but labor remains adamant in its attitude. Therefore no employment examinations of any type have been made on any employees of West Coast Maritime Commission shipyards.

There is thus presented, within the Maritime Commission's jurisdiction, an unusual opportunity to compare the results of preplacement physical examinations performed on about 100,000 men and women over a period of three to four years, with a similar group in the same industry which has not been subjected to

This constitutes part of a thesis prepared at Harvard School of Public Health for Master of Public Health degree.

Professor Philip Drinker, chief health consultant, United States Maritime Commission, was of considerable assistance in completing the study.

Dr. McGill formerly was assistant chief health consultant, United States Navy—Maritime Commission Contract Shipyards, Gulf Coast Region.

The opinions expressed are those of the author and do not necessarily conform to those of the United States Public Health Service or the United States Maritime Commission.

Mr. Howard Gates, chief, Casualty Insurance Section, Division of Insurance, United States Maritime Commission, was of invaluable help in furnishing the compensation carriers' reports from which the data were obtained.

1. Minimum Requirements for Safety and Industrial Health in Contract Shipyards, U. S. Navy, U. S. Maritime Commission, Washington, D. C., Government Printing Office, 1943.

examinations. It is unlikely that a comparable group of data has been previously available.

Absolute necessity has forced the shipbuilding industry to employ the physically handicapped or imperfect and to place much emphasis on maximum utilization of man and woman power through the elimination of lost time due to preventable causes. The industrial safety program has resulted in substantial savings through protection from industrial accidents and diseases, but the Maritime Commission officials realized that an important basis for the control of both occupational and nonoccupational illness and injury is the effective utilization of physical examinations. To activate such a program they adopted the newer philosophy of preplacement examinations and accepted as a working basis the specific objectives of such examinations, as outlined by the Council on Industrial Health of the American Medical Association,² which are:

1. To facilitate placement and advancement of workers in accordance with individual physical and mental fitness.
2. To acquaint the worker with his physical status and to advise him in improving and maintaining personal health.
3. To safeguard the health and safety of others.
4. To discover and control the effects of unhealthful exposure.
5. To promote cooperative support and understanding of industrial health practices by employer and employee alike.

The examination procedures may not have fully achieved these broad ideals, but most of the yards doing preplacement examinations have had as a prime objective the fitting of every worker to the type and quality of work according to his or her ability to perform such work continuously, without undue impairment to self or fellow workers. Numerous wartime exigencies have presented obstacles to the fullest realization of the potential benefits.

EXAMINATION PROCEDURE

The steps in the employment procedure, as generally practiced, are as follows: The applicant is first given a preliminary interview by the employment department to determine his general qualifications for work. He is then referred to the medical department for examination and classification, after which he is sent back to the employment department for hiring and placement within his physical capacity, or rejection. If rejected, the considerable expense and time of completing employment, including finger printing, photographing and issuing a badge, are thus eliminated.

The examination usually includes a brief medical and personal history signed by the patient. Considerable variation exists in the thoroughness with which this is done, but a nonmedical clerk usually spends two to four minutes obtaining the data. The record of height, weight, blood pressure, pulse rate, hearing and visual acuity, temperature and the like is usually made by a trained assistant or a nurse in about ten minutes for each worker.

When the preliminary tests are concluded, the applicants are examined by the yard physician. The men are usually examined, stripped, singly or in groups, special search being made for hernias, varicosities, deformities and cardiovascular or neuropsychiatric defects. Examinations of women are usually not so complete as indicated for the men. Examinations have not always been performed in the most desirable manner, sometimes being little more than medical inspections, especially

when one physician, with his nursing and clerical helpers, is required to examine up to 160 workers daily. Placement following the examinations has not always been ideally practiced, but in all yards some effort has been made in this direction.

From the examination data the physician classifies the applicant in accordance with the system generally adopted by industry:

- A. Fit for any work in the yard.
- B. Physically underdeveloped or with correctible defect: otherwise fit for any work, or capable of all but specifically excepted jobs.
- C. Fit only for certain jobs when approved and supervised by the medical or safety department.
- D. Physically unfit for any work in the yard.

The rejection rate, or proportion of those classified D, has averaged less than 3 per cent. This is an indication of the liberal physical standards used and of the general success of the practice of preplacement physical assessments. The National Association of Manufacturers³ states that the average rejection rate of 1,154 plants in 1939 was 4.4 per cent. This rejection rate was before 11,000,000 younger men were inducted into the armed forces, leaving a larger proportion of persons physically defective to be hired by industry. In personal communications from other large industrial groups, I am informed that their present rejection rates are somewhat higher than the 3 per cent now experienced in the Maritime Commission yards.

GEOGRAPHIC DISTRIBUTION

Of the ten shipyards considered in this study, five, located on the East and Gulf coasts, required preplacement examinations. The other five, on the Gulf and West coasts, which did not require examinations, are henceforth considered as the control yards. Comparison of these similar sized groups of workers must necessarily be on an arbitrary basis. The innumerable personal and socioeconomic factors influencing two groups of people in such different geographic areas cannot be statistically evaluated.

Four of the yards doing examinations and two in the control group are located in the Southern states. For many years it has been generally believed that this geographic area is below the median level of the United States in many of the important socioeconomic classifications. It is known that this same area presents an unusually high incidence of many diseases, especially dietary deficiencies, venereal diseases, parasitic diseases and tuberculosis. Medical care facilities also are known to be insufficient. These are mentioned to indicate some of the factors that might possibly influence the results on which this study is based. It is generally believed that a lowered physical well-being increases accident proneness. If the Southern, and to a lesser extent the Eastern, shipyards have employees of lower physical status than that of the Western yards, they may be expected to have more serious accident claims, including hernias, presented for compensation adjustment, other in-plant safety and health hazards being equal.

EFFECTS OF EXAMINATIONS ON COMPENSATION INSURANCE RECORDS

The accident frequency records, as listed in table 1, for each yard under consideration for the period 1943-1944, were taken from reports compiled by the Division of Industrial Hazards, United States Department of

2. Industrial Health Examinations, J. A. M. A. 125:569 (June 24) 1944.

3. A Report of Survey of 2,064 Industrial Establishments, New York, National Association of Manufacturers, 1941.

Labor, from monthly reports furnished them by the individual yards. The "Minimum Requirements,"¹ paragraph 4.13, b, defines accident frequency as

$$\frac{\text{Number of Disabling Injuries} \times 1,000,000}{\text{Total Man Hours Worked for Period Covered}}$$

A disabling injury is one which results in a person being unable to report for work on the next regular shift or

subsequent to the initial return to work. The yards without examinations more nearly group about their two year mean frequency rate (21.8) than do the examination yards about their mean rate (23.9), although the difference is not significant.

Table 2 shows the quarterly loss ratios as furnished by the Casualty Insurance section of the Division of

Insurance of Maritime Commission. This is the ratio that the total amount of incurred expenses (which includes incurred indemnity and medical losses) bears to the total compensation insurance premiums. The total incurred losses and expenses include serious and nonserious open and closed claims and contract medical costs. However, incurred indemnity losses vary considerably with the workmen's compensation laws and regulations of each state.

These loss ratios are used by compensation insurance companies to measure the efficiency of the preventive and corrective medical programs of the yards. Other factors being equal, a high loss ratio indicates more numerous and more serious accidents and costlier medical treatment. The employer is interested in the loss ratio as an indication of the protection provided and of the quality of medical service given his employees. The employee also is concerned in the loss ratio, as it reflects the protection and service afforded him by the industrial safety program and medical department. If preplacement examinations are of value in protecting

† Serious cases are those of over \$300 total cost.

the worker, such protection should result in a lowered insurance loss ratio.

Comparison of the loss ratios (table 2) for both groups of yards shows this to be true. For the nine quarterly periods Oct. 1, 1942 to Jan. 1, 1945 the examination yards range from a low of 12.2 to a high of 58.5. The averages of these five yards vary from 26.06 to 35.4, with a mean of 32.12. For the same quarterly period the loss ratios of the control yards range from 28.9 to 82.8. The averages of these yards vary from 33.9 to 71.6, with a mean of 48.01. It is statistically significant that the control group mean loss ratio is 50 per cent higher than that of the examination yards.

Variation in compensation costs is demonstrated by table 3, which shows the range of totals of incurred indemnity and medical losses, closed claims, in various states as reported in the compensation carriers' quarterly reports to the Maritime Commission. It will be noted that considerable variation exists between the minimum and maximum costs of closed compensation claims for death, serious eye injuries and other serious accidents. The range for hernias is not so great. As cases costing \$300 or more are reported as serious, the minimum figures are limited to items above this sum. These variations result from the different application of differing workmen's compensation laws by the respective state commissions. This makes it impossible to compare the yards on the basis of total compensation

expenses but does not preclude utilization of the total number of claims for serious injuries.

A principal item of importance in any tabulation of compensation losses is the frequency of hernias, especially inguinal. The occurrence of hernias included in the total incurred losses and expenses and the total number of serious closed compensation cases have been tabulated from the compensation insurance companies' quarterly report. To make these results comparable, an average of serious cases and hernias per month, reduced to a ratio per thousand employees, is presented for each yard.

$$\frac{\text{Hernias (or serious cases)} \times 1,000}{\text{Number of months} \times \text{average monthly employment}} = \text{Hernias (or serious cases) per thousand employees per month.}$$

The comparisons have been standardized by using employment figures available in the Maritime Commission Division of Shipyard Labor Relations up to January 1945.

These data are listed for both groups of yards in table 4, and ratios are compared in the graph. The total control group of 106,238 average employment had an average of 4.33 hernias and 35.10 serious cases per month, with a ratio of 0.21 hernias and 1.69 serious cases per thousand men monthly. The group of yards doing examinations, with an average employment of 107,921 per month, had an average of 1.47 hernias and 12.87 serious cases per month, with a ratio of 0.06 hernias and 0.58 serious cases per thousand men monthly. The ratio for hernias is over three times as high and for serious cases almost three times as high in the control yards as in the examination yards, indicating a consid-

erable reduction of these two common and expensive items of compensation costs in the yards requiring examinations.

Special attention is directed to the comparison of yards 3 and 10. These yards, a few hundred miles apart in different states, are as nearly alike as any under Maritime Commission control. The two are operated

by the same company. Both are located in shipbuilding communities; socioeconomic factors are comparable. Workers are drawn from the same geographic areas. For the purpose of this study they are identical except for their medical programs.

Yard 3 developed a medical program, including preplacement examinations, during construction of the yard and has continued to expand the medical activities with full cooperation of the management. By contrast, full cooperation of management of yard 10 was not extended the medical department until the ship construction program was well under way. As a result, the medical activities were not permitted to develop to maximum usefulness. The results of this antithesis are clearly shown in analysis of data of table 4.

Yard 3 had an average of 0.39 hernia and 6.00 serious cases per month, ratios of 0.03 and 0.46 respectively, per thousand men monthly. Yard 10 had an

Ratios, hernias and serious cases. Numbers refer to listing of yards of table 4.

average of 2.26 hernias and 14.04 serious cases per month, ratios of 0.17 and 1.04 respectively per thousand men monthly. Hernias were thus over five times (5.7) as frequent and serious cases over two times (2.3) as frequent in yard 10 as in yard 3. Loss ratios (table 2) at the former yard range steadily upward from 30 to 69.59; at the latter this increase is from 20 to 33.53—from 50 per cent to 100 per cent less than the sister yard which did not perform preplacement physical examinations. These loss ratios reflect the expenses of compensation insurance payments and are thus an expression of the working health of the shipyard employees.

Yard 5 had the next lowest hernia ratio, 0.04, and the highest serious case ratio, 0.88, of any examination yard. These are much lower than ratios at yard 10 in the same state, indicating that the difference between yards 3 and 10 was not due exclusively to any differences between the respective state compensation commission policies. Similarly, the differences between yards 5 and

10 are not due to varying compensation practices but to in-plant factors.

Further comparison with the accident frequency rates for yards 3 and 10 (table 1) shows the former to be significantly lower than the latter, with 1943 annual rates of 16.4 and 30.1 respectively. The monthly rates for 1944 show this difference to be continuous, 7.5 and 22.2 respectively.

It is not presumed that physical examinations or even the medical programs are exclusively responsible for the contrast between these two groups. However, it cannot be denied that the more complete medical programs of the examination yards contributed to their lower loss ratios and to their more favorable experience with hernias and serious cases, even though the completeness of these programs may have differed only by the examinations.

SUMMARY

1. Five shipyards which conducted preplacement physical examinations were compared with a similar group without examinations. Average employment of each group exceeded 100,000. Compensation insurance loss ratios, frequency rates and actual occurrence of hernias and severe cases in the compensation carriers' reports of losses incurred during a three year period were used as the basis of this comparison.

2. The average loss ratios for control yards are about 50 per cent higher than those of the examination yards.

3. The average number of hernias and serious cases per month, and the rate of these per thousand men monthly, are about three times as high in yards without examinations as in yards with preplacement physical examinations.

Clinical Notes, Suggestions and New Instruments

THE CRUSH SYNDROME

REPORT OF FATAL CASE WITHOUT COMPRESSION INJURY

LIEUTENANT COLONEL CLIFFORD C. WOODS

CAPTAIN CLARE H. TAYLOR

AND

CAPTAIN R. B. CHESNICK

MEDICAL CORPS, ARMY OF THE UNITED STATES

The crush syndrome, also known as compression syndrome with traumatic edema, has been described in British and American literature since 1940. The Medical Research Council of Great Britain has collected data on 100 cases. The typical case is fairly clearcut, and its differential diagnosis is not usually difficult. A patient is admitted with a history of compression injury, usually of an extremity. Definite absence of shock with pronounced hemoconcentration is present.

The pathologic physiology is somewhat better understood than the knowledge of the shock syndrome itself. Often the syndrome follows an initial shock picture. The usual sequence of events is as follows:

Following the recovery from the shock picture, there is a gradual diminution in the urinary output. The urine will be tinted and contain some red blood cells and also a sediment which is almost diagnostic of the syndrome. This sediment, if carefully examined spectroscopically, will prove to be myohemoglobin. The patient's blood pressure is well maintained, a moderate anemia may manifest itself and a progressive azotemia is noted. A reevaluation and history of these patients may reveal a story of prolonged compression of an extremity, the thorax or the abdomen itself. If an extremity has been compressed, it will be noted that the victim, once comfortable after the control of shock and proper control of bleeding, will react after the removal of the constricting tourniquet. The part will swell and the blood pressure will tend to fall, although

temporarily maintained by vasoconstriction. Hemoconcentration and oligemia may set in because of loss of plasma into the swollen tissues. Increased tissue tension may partially obliterate the pulse, and the part may become cold.

In some patients, pressure damage may be manifested by discoloration and vesication. In still others the objective signs of injury may be concealed. Damage to some of the abdominal contents may require extensive operative surgery and resection. The patient reacts favorably and may be well on the way to recovery. From a few hours to several days after the initial treatment the urine becomes cloudy and a brown sediment forms. A spectroscopic analysis of this sediment will show it to be myohemoglobin. Further studies will demonstrate pigment casts which are at first hollow tubes and later covered by epithelial cells. Other urinary findings include a progressive increase in potassium and creatinine, most of these products resulting from degeneration of muscle tissue. Blood studies reflect a renal failure. Nitrogenous retention becomes progressive and the carbon dioxide combining power is low at first but rises thereafter. A terminal fall in blood pressure may result from the retention of acids derived from the damaged tissue.

According to Bywaters,¹ one third of the cases go on to spontaneous recovery and suggest a moderate degree of muscle damage. The disturbance of urinary functions and blood chemistry reverses itself with or without any therapy. In severe cases, however, sometimes as late as the sixth or seventh day, renal function fails and azotemia and urea will supervene.

The gross and microscopic pictures of the kidneys are quite characteristic. Grossly the kidneys are large, pale and swollen. The capsules are tense. The microscopic picture shows local areas of tubular necrosis and pigmentary casts about the loops of Henle, the distal convolutions and the collecting tubules. The pigments were found by Bywaters, Delory and Remington to have specific spectroscopic characteristics of an intracellular hemin compound which is responsible for oxygen storage in the muscles. This substance, which is much lighter than hemoglobin, is easily filtered through the glomeruli but tends to precipitate in the excretory tubules.

Changes in muscles may be either macroscopic or microscopic. Grossly the muscles may appear to be normal, but microscopic examination shows varying degrees of patchy microscopic damage. In serious damage the muscle will be swollen, pale, friable, hemorrhagic and sharply demarcated from the surrounding normal tissues. The microscopic appearance may show all the changes from edema and loss of cross striations to complete necrosis. Similar damage to that just described may occur following accidents in which arterial injuries result in arterial spasms and no apparent gross tissue damage. The therapy of this curious syndrome is similar to that utilized in prevention of urinary failure following the transfusion reaction or the use of sulfonamides. The chief objective is to maintain an adequate alkaline urinary output. This should be done, if possible, before the release of the tourniquet. If renal failure ensues, all therapeutic efforts usually fail, although some patients have been known to recover with urea levels of approximately 500.

This case is presented because of its unusual clinical course, the delay of manifestation of urinary failure, the absence of external evidence of compression and rather typical pathologic pictures of muscle and kidney damage. The patient, a healthy white infantry soldier aged 21, was admitted to the hospital after being thrown from a jeep while on a field problem and sustaining a severe blow to the abdomen, back and right arm. He was in evident shock, with a pulse rate of 120 and blood pressure of 80/60. He was pale, his skin was clammy and he complained of pain in the right shoulder and right side of the neck. Moderate abdominal tenderness and rigidity, with dullness in both flanks, were present. There was diminished peristalsis. Significant laboratory findings at the time of his admission were red blood cells 4,430,000, hemoglobin 90 per cent, white blood cells 18,000, with 83 per cent neutrophils and 17 per cent lymphocytes. The urine was essentially normal. X-ray examinations

1. Bywaters, E. G. L.: Ischemic Muscle Necrosis, J. A. M. A. 124: 1103 (April 15) 1944.

of the abdomen revealed an indefinite increase in density in the left upper quadrant. He was matched for transfusion and, following a diagnosis of a ruptured viscus, he was given both blood and plasma. With a systolic pressure of 100, the abdomen was opened through a left rectus incision under gas-oxygen anesthesia. The entire peritoneal cavity was found to be filled with blood. It was conservatively estimated that 3 quarts of blood had been lost in the abdominal cavity. As no perforations of a viscus were found, 1,500 cc. of the abdominal blood was aspirated, citrated and given back as a transfusion. In addition, he received 1,000 cc. of blood from a compatible donor. Further inspection of the abdomen revealed a huge hematoma in the transverse colon originating from a torn middle colic artery. The entire circulation of the transverse colon and parts of the descending colon had been destroyed. The pancreas was found to be badly contused and hemorrhagic. The transverse mesocolon was ligated in sections, and the entire transverse colon and about one half of the descending colon were exteriorized. The patient's immediate postoperative condition was better than before operation. His blood pressure was 130/80 and pulse rate 100. He was started on intravenous 5 per cent glucose and saline solution and continuous gastric suction and was given 2,000 cc. of blood during the next four days. Sulfadiazine and penicillin, in divided doses, were begun. On the second postoperative day, following symptoms referable to his lungs, an x-ray revealed atelectasis of the right base. This condition responded rapidly to treatment. The exteriorized colon was removed by cautery on the third postoperative day. On the fifth postoperative day his condition was good except for moderate abdominal distention, which was easily controlled by means of a Miller-Abbott tube. His blood chemistry was normal. On this, the fifth postoperative day, his urine first became smoky. Urinalysis showed 10 to 15 red blood cells per high power field and the urinary output at this time averaged 1,200 to 1,400 cc. for the twenty-four hours. Twenty-four hours later, however, the output had dropped to approximately 120 cc. In spite of this his colostomy was functioning well, the Miller-Abbott tube had been removed and he tolerated a soft diet. Efforts were made to stimulate the excretion of urine by the use of intravenous hypertonic solutions and sodium lactate, but the output never rose higher than 200 cc. in twenty-four hours regardless of the fluid intake. The ureters were both catheterized, and this procedure was followed by a large quantity of blood in the urine. On the tenth postoperative day, examination of the urine revealed creatinine 35 mg., albumin 300 mg. per hundred cubic centimeters and numerous red blood cells. On this date the nonprotein nitrogen was 33. On the eleventh postoperative day it rose to 190, creatinine 7 and on the twelfth postoperative day the urea nitrogen was 79.1 and creatinine 7.5. This increase in nitrogenous end products was progressively upward until his death on the fourteenth postoperative day. Death was preceded by the appearance of moderate pulmonary edema and edema of the extremities and trunk. The terminal phase was quite sudden and apparently due to heart failure.

At autopsy it was found that the heart, spleen and pancreas were all edematous. Moderately extensive hemorrhages were noticed beneath the mucosa of the calices and pelvis of each kidney. It was felt that this change was due to trauma during catheterizations. Grossly both kidneys were enlarged, pale and quite edematous. Section through the capsule resulted in bulging of the cortical surface. On microscopic examination a generalized edema was noticed through both kidneys, involving the greater portion of the interstitial tissue and the tubular elements. Large masses of round cells and occasional polymorphonuclear cells were present between the collecting tubules. Many loops of Henle and collecting tubules were almost completely filled with granular and homogeneous pigments which almost completely obliterated the lumens, this process being more evident in the medulla than in the cortex. The medulla contained numerous tubules which were filled with red blood cells, round cells and polymorphonuclears. Grossly both psoas muscles showed some evidence of edema but no other changes. Specific iron stains were negative. On microscopic examination all manner of transition from the normal was seen. The changes included complete necrosis of some of the muscle fibers,

loss of cross and longitudinal striations in others and partial necrosis in still others. The character of the necrotic muscle also varied, some fibers appearing as amorphous masses situated between normal muscle fibers, while others consisted of masses of loose basophil staining granular pigments. Swelling of the muscular nuclei and proliferation of the endomysium was evident in adjacent intact fibers. Iron stains of the presence of hemoglobin pigments in the muscle and kidney were negative. Reticulum stains demonstrated degeneration of not only the muscle fibers themselves but of the supporting stroma.

SUMMARY

1. A soldier was thrown from a jeep. He was brought to the hospital immediately. There was no prolonged compression of an extremity.
2. Renal failure developed nine days after his injury and his operation.
3. Advanced degeneration was demonstrated in both kidneys and psoas muscles.
4. Typical cellular and obstructive lesions of the renal tubules were found.

CONCLUSION

The case presented apparently demonstrates a clinical picture of the crush syndrome in which anuria was delayed until approximately the ninth day. The failure to find necrotic or degenerative muscle on gross inspection and the subsequent finding of extensive degeneration of the psoas muscles suggest a vasospastic phenomenon with ischemic necrosis. A factor which may have contributed to the degeneration of the muscles was the presence of the overlying hematoma.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

ALLERGENIC PREPARATIONS (See New and Nonofficial Remedies, 1944, p. 35).

The following extract now stands accepted:

WYETH, INC., PHILADELPHIA

Allergenic Extract: The following extract is marketed in treatment packages of five 1 cc. size cartridge ("Tubex") vials representing graduated concentrations, namely 100, 1,000, 6,000, 20,000 and 20,000 pollen units per cubic centimeter. Also in treatment packages of five 1 cc. size cartridge ("Tubex") vials, each representing 20,000 pollen units per cubic centimeter.

Ragweed Combined (Giant and Short Ragweeds, in equal proportions).

The pollen is weighed and extracted with ether. After removal of the ether the material is mixed with the extracting liquid, consisting of a 0.5 per cent sodium chloride solution containing approximately 0.28 per cent of sodium bicarbonate and 0.5 per cent of phenol and covered with toluene. After three days the extract is subjected to Berkefeld filtration and tested for sterility. Standardization is on the basis of pollen units, 1 pollen unit being equivalent to 0.001 mg. of pure pollen.

MENADIONE (See New and Nonofficial Remedies, 1944, p. 638).

The following dosage forms have been accepted:

SHARP & DOHME, INC., GLENOLDEN, PA.

Tablets Menadione: 1 mg.

Solution Menadione (in peanut oil) 2 mg. per cc.: 1 cc. ampuls.

SULFADIAZINE (See New and Nonofficial Remedies, 1944, p. 178).

The following dosage form has been accepted:

MCNEIL LABORATORIES, PHILADELPHIA

Tablets Sulfadiazine: 0.5 Gm.

THIAMINE HYDROCHLORIDE (See New and Nonofficial Remedies, 1944, p. 608).

The following dosage form has been accepted:

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

Tablets Thiamine Hydrochloride: 1 mg.

SATURDAY, NOVEMBER 3, 1945

TYPHUS THERAPY

The rickettsias of typhus are obligate intracellular parasites that multiply only in the interior of host cells. In 1937 Zinsser and his associates¹ of Harvard Medical School showed that the rate of intracellular multiplication of rickettsias in Maitland tissue cultures is determined by the metabolic rate of the host cells. Under conditions of high metabolic activity, as determined by the rate of acid formation or of oxygen consumption, little or no multiplication of the intracellular parasites takes place. Only under conditions of reduced metabolic activity was active multiplication noted. This observation finds partial confirmation in the subsequent demonstration² that riboflavin deficiency, which slows down metabolism by interfering with internal respiration, reduces the normal resistance of rats to rickettsia infection.

In order to find substances with the opposite effect, Greiff and his associates³ of St. Louis University School of Medicine have recently studied the influence of various vitamins, enzymes, enzyme activators and related substances on the rate of multiplication of typhus rickettsias in the yolk sac of the developing chick embryo. Groups of five day embryonated eggs were inoculated in the yolk sac with 0.1 cc. of a standard rickettsial suspension. At various intervals after this inoculation half of the members of each group were injected with various concentrations of the substances to be tested, the other half serving as untreated controls. The rate of multiplication was estimated from rickettsial counts of the yolk sac membrane made at suitable intervals after inoculation. Thus, in untreated control eggs a count of less than 1 rickettsia per oil immersion field was usually recorded during the first two days, increasing to from 10 to 100 rickettsias per field by the fourth day and to between 8,000 and 12,000 per

field by the eighth day. Death usually took place on the seventh or eighth day.

Greiff found that most of the vitamins, enzyme activators and related substances thus far tested neither accelerate nor retard this control rate of multiplication. Among these negative substances are biotin, riboflavin, thiamine hydrochloride, cholin chloride, orthoaminobenzoic acid and meta-aminobenzoic acid. The only positive inhibitor thus far found is para-aminobenzoic acid. After yolk sac injection of 3.3 mg. of this B vitamin fraction the oil immersion count rarely exceeds 1 rickettsia per field at any time during the first fifteen days. All embryos remain alive until the end of the experiment. This is an antirickettsial titer equal to that previously reported from yolk sac injections of 325 Oxford units of penicillin.⁴

The therapeutic value of para-aminobenzoic acid was further tested on groups of mice inoculated intraperitoneally with multilethal doses of murine typhus rickettsias. Half of each group (controls) was fed throughout the experiment on Purine dog chow. Immediately after injection of the rickettsias the other half was placed on the same diet plus 3 per cent para-aminobenzoic acid. Of 23 normally fed (control) mice, all died of typical typhus infection on or before the seventh day. Only 1 of the 23 para-aminobenzoic acid fed mice died during this or subsequent periods, a survival rate of practically 100 per cent.

Greiff believes that this remarkable therapeutic effect was due to metabolic stimulation of host cells. He, however, disclaims priority for this discovery. Since completing his experiments he has learned that similar favorable effects from para-aminobenzoic acid therapy were previously described in unpublished confidential reports now on file with the United States of America Typhus Commission.

INTRACELLULAR ANTIBODIES

In 1913 Much,¹ Manwaring² and others reported experimental evidence which led them to propose a tentative theory of "partial antibodies" to account for the phenomena of acquired immunity to tuberculosis. Specific agglutinins, precipitins and other so-called antibodies are found in the circulating blood; the theory assumed that the really essential bactericidal factors are found only in the fixed tissue cells. In support of this theory it was shown² that tubercle bacilli, while rapidly lysed in the peritoneal cavities of tuberculous animals, are not lysed in the animal's serum. Manwaring found that the acquired power of intraperitoneal lysis of tubercle bacilli cannot be transferred to normal animals even by total blood transfusion. The essential

specific bacteriolysins present in the immunized peritoneal cells apparently are not given off in detectable amounts into the blood stream; or, if given off, they presumably are destroyed or otherwise rendered inactive in much the same way that leukocytic extract is inactivated by normal blood serum.³

This tentative theory of essential nonhumoral antibodies in acquired immunity to tuberculosis is supported by data recently reported by Chase⁴ of the Rockefeller Institute. Chase rendered guinea pigs hypersensitive to tuberculin by subcutaneous injection of killed tubercle bacilli suspended in liquid petrolatum. By the end of five to nine weeks, cutaneous reactivity to tuberculin was pronounced. Exudates were then induced in the peritoneal cavities by intraperitoneal injections of liquid petrolatum. After forty-eight hours the peritoneal cavities were washed out with heparinized Tyrode solution containing gelatin and 10 per cent normal guinea pig serum. The exudate thus obtained consisted mainly of large mononuclear cells. These cells were washed in serum-Tyrode solution and immediately injected intraperitoneally or intravenously into normal albino guinea pigs. The recipients were tested at daily intervals with old tuberculin. After a latent period of from two to three days following intraperitoneal injection (or twenty to thirty-six hours after intravenous injection) tuberculin hypersensitivity became established in the skin of the recipient. The passive hypersensitivity reached its maximum about forty-eight hours later. At this time the routine test dose of old tuberculin gives rise to a diffuse, indurated erythematous reaction. The hypersensitivity gradually fades after reaching this maximum.

Chase found that the intensity of the transferred cutaneous hypersensitivity varies with the volume of peritoneal cells and with the degree of sensitivity of the tuberculous donor. Similar transfer was never effected with the donor's serum or with the peritoneal exudates of nontuberculous guinea pigs. The peritoneal cells are inactivated by heating to 48 C. for fifteen minutes or by prolonged storage at refrigerator temperature. In addition to the peritoneal cells, cells from the spleen or lymph nodes of tuberculous animals are capable of passive transfer of tuberculin hypersensitivity.

Cellular transfer of acquired sensitivity was first demonstrated by Landsteiner⁵ in 1942. He found that exudates from the peritoneal cavities of guinea pigs previously sensitized to a number of simple chemical substances would cause homologous specific skin sensitivity if injected intravenously, intraperitoneally or intracutaneously into normal guinea pigs. The nature of the presumptive anaphylactic antibody present in these peritoneal cells is still undetermined.

Current Comment

DIPHTHERIA CAN BE ELIMINATED

In 1943 the death rate from diphtheria at all ages fell below 1 per hundred thousand for the first time.¹ At the same time the death rate in children under 10, in whom the disease is most frequent, has fallen below 5 per hundred thousand. Wide variation in the size of the diphtheria rates among children occurs, however, in different states: using the average figures for 1940-1942, Delaware without any deaths from diphtheria under 10 during these three years appeared at one extreme and, at the other, Arkansas and South Carolina with 13.7 deaths per hundred thousand and Oklahoma with a rate of 13.5. The available methods for control of diphtheria are sufficient to allow the complete elimination of this disease in the United States. An analysis of fatalities among children insured in a large life insurance company indicated that two factors were principally involved: delay in treatment (when the physician was not called until the fourth day of the disease or later) and the use of insufficient antitoxin. The application of modern immunization methods of susceptible persons on a countrywide basis would serve to eradicate the disease; meanwhile, emphasis on the importance of sufficiently early administration of antitoxin in adequate doses would help to prevent the unnecessary deaths of some 1,000 American children who still die of diphtheria annually.

ACTA SCANDINAVICA

In the past few months THE JOURNAL has received, thanks to more normal postal relations between Europe and the United States, a number of issues of the *Acta Scandinavica* for 1945 with an unusually large number of supplements. All the supplements, with the exception of one from Helsinki, Finland, are from Sweden, the one Scandinavian country to escape participation in the global war. The clinical papers and the supplements reflect the excellence of the medical institutions and the scientific character of clinical investigations usually found in the *Acta*. Of the ten supplements, eight are in English and two in German. Among the supplements to the *Acta medica* may be mentioned one by Nils Skiold on the clinical features and the origin of erythema nodosum, based on a study of 345 patients. Skiold shares the general concept of the condition as a nonspecific allergic phenomenon but would include in this concept erythema multiforme as well. Hans Forssman presents a study on hereditary diabetes insipidus in the course of which he had traced 5 pedigrees with 83 genebearers, involving investigation of 5,500 persons. An interesting study by Karl Axel Ekblom concerns a common but little recognized syndrome of "restless legs." Among the supplements to the *Acta chirurgica* may be mentioned an extensive study by S. Bruzelius on dicumarol from the Surgical Clinic in

1. Statistical Bulletin, Metropolitan Life Insurance Company, August 1945.

Lund. The frequency of thrombo-embolism was reduced to one third of that in the control groups, while the incidence of fatal pulmonary embolism has fallen from 0.49 per cent in two control groups to 0.16 per cent in the group treated prophylactically with dicumarol.

THE HEALTH OF THE CHINESE IN SAN FRANCISCO

The San Francisco department of public health has issued a report for the twenty year period 1924-1943 for Chinatown in San Francisco.¹ The population estimate for this district is 18,000. The Chinese as a group have continued to live under definitely substandard conditions in the area first chosen as a site for Chinatown. War industry brought a rise in income level, with more families able to assume higher living costs but unable to find better living quarters. Conditions of substandard housing and overcrowding continue to exist although the economic state has improved. In Chinatown the birth rate per thousand of population has fallen from a peak of 40.2 in 1924 to the low rate of 11.8 in 1937, with a gradual upswing to 18.8 in 1943. Since 1937 it has approximated more closely the rate for the entire city of San Francisco. In the past fifteen years Chinese births in hospitals have increased 320 per cent. At the same time, citywide births in hospitals increased 21 per cent. The younger American born Chinese parents are more eager to accept the maternity and child welfare programs, but the influence of the older foreign born parents continues to restrict educational programs. The Chinese infant mortality rates exceed those for the city as a whole. In 1936 the Chinese rate was exactly twice that for the city. In the following years the rate steadily declined to a level that compares favorably with the rest of the city. Respiratory infections and prematurity consistently constitute the principal causes of death in Chinese infants. The relative rank of the principal causes of death among the Chinese has altered since 1930, when tuberculosis indisputably outranked all others, with nephritis (chronic), heart disease, pneumonia and cancer following in order. In 1943 heart disease led the list, followed by cancer, tuberculosis, nephritis and pneumonia. In 1929 the average age at death for the city as a whole was 52.4 years and for the Chinese 41.7; in 1943 it was 57.7 and 50.2 respectively. The death rate has fallen from 22.4 per thousand in 1924 to 12.9 in 1943. The citywide rate was 12.7 in 1943. Except for tuberculosis there is comparatively little spread of contagious disease in the Chinatown area. When increased incidence of communicable diseases is reported for the entire city there is an increase in Chinatown as well, though to a comparatively less extent. In the last two citywide epidemics of poliomyelitis not a case was found among the Chinese. Few cases of influenza were reported from this area. Trachoma and acute conjunctivitis are reported with great frequency. Tuberculosis still constitutes one of the major health problems in the Chinese area. In 1939 the cases of tuberculosis

seen at the Chinese Health Center were far advanced. Now the cases seen are frequently of an early type that can benefit from efficient care. The death rate from pulmonary tuberculosis among Chinese shows about the same rate of decrease as that for the entire city, but the rate persists much higher for Chinatown. Any program of public health recommended for the entire city should be effective in Chinatown as well for the Chinese people, who have responded well to public health activities, which have been of prime importance in improving the health of the Chinese.

HEMORRHAGE FROM PUNCTURE BIOPSY OF THE LIVER

One great danger of biopsy of the liver, now practiced extensively by aspiration, is hemorrhage from the puncture. According to Raby¹ 7 instances of fatal hemorrhage have been reported, all in advanced or severe cases of carcinoma or pernicious anemia. Vitamin K was not given in any case before the puncture. The coagulation time was determined beforehand in only 1 case, and here clotting was delayed. Raby himself reports in detail a fatal intraperitoneal hemorrhage from puncture of a portal branch near the anterior surface of the right lobe of the liver in a woman aged 79 with jaundice of uncertain origin. The coagulation time before puncture was normal. The patient died thirty-six hours after the biopsy in spite of hemostatic treatment and blood transfusion. Raby also reports the death of a man aged 85 with senile dementia but without any hemorrhagic tendencies, which occurred three days after biopsy of the liver. The symptoms seemed obscure and postmortem did not reveal any primary cause of death. Bacteriologic examination was not made. Clearly, puncture of the liver is not without danger, especially in old persons. Precautions should never be neglected when puncture is indicated. Hemorrhagic tendencies should be excluded. Raby recommends also that the patient's blood group be determined before puncture and that the patient be watched closely after the puncture in order that transfusions may be made if necessary without delay.

N. N. R. 1945 AND REPRINT OF COUNCIL REPORTS FOR 1944 NOW AVAILABLE

Physicians, pharmacists, manufacturers of pharmaceuticals and indeed all who are interested in drug therapy will be pleased to know that these two annual publications of the Council on Pharmacy and Chemistry are now available. These volumes are indispensable to any one desiring to keep abreast of the latest advances in therapy. Their unusually late appearance is the result of wartime difficulties, including not only a shortage of paper and scarcity of mechanical personnel but also the fact that practically all Council members have been importantly and increasingly engaged in the war effort. The unselfish devotion of the Council members is worthy of the cause they represent—the support of rational therapy.

MEDICINE AND THE WAR

ARMY

ARMY MEDICAL RESEARCH AND DEVELOPMENT BOARD FORMED

A board to be known as the Army Medical Research and Development Board was constituted in the Office of the Surgeon General on September 1. The board is to be responsible for the planning and general supervision of all Medical Department research and development activities. Its membership will include the chiefs of the various professional services and divisions of the Office of the Surgeon General, the Air Surgeon, the Ground Surgeon, the chairman of the Division of Medical Sciences, National Research Council (by invitation), and the chairman of the Committee on Medical Research, Office of Scientific Research and Development (by invitation). The board has two operating divisions, the Research Division and the Development Division, to carry out its plans.

It is the intent of the Surgeon General to carry on an active program of research and development during the postwar period, and the new board should provide the means for maximum coordination of effort within the military service and cooperation with civilian and federal research agencies. The immediate tasks facing the board are three in number. Essential research must be continued in the existing Medical Department research and development laboratories in spite of the personnel difficulties of the period of demobilization. Plans must be made and implemented for the continuation or actual expansion of research and development in the postwar period. The demobilization of the Office of Scientific Research and Development necessitated finding other sponsorship for those CMR research contracts which warrant continuation even though hostilities have terminated. A sizable group of these contracts will be taken over by the Medical Department and administered by the Army Medical Research and Development Board.

HOSPITALS NAMED FOR REFRESHER TRAINING COURSES

Major Gen. Norman T. Kirk, Surgeon General of the Army, recently notified the commanding officers of the following hospitals that their medical services had been approved for the professional refresher training courses of Medical Corps officers to extend over a twelve weeks period:

Cushing General Hospital, Framingham, Mass.
Mason General Hospital, Brentwood, Long Island, N. Y.
Valley Forge General Hospital, Phoenixville, Pa.
Kennedy General Hospital, Memphis, Tenn.
Newton D. Baker General Hospital, Martinsburg, W. Va.
Percy Jones General Hospital, Fort Custer, Michigan.
Winter General Hospital, Topeka, Kan.
McCleskey General Hospital, Temple, Texas.
DeWitt General Hospital, Auburn, Calif.

Medical Corps officers desiring refresher training in neuropsychiatry will be permitted to serve the entire twelve weeks in the neuropsychiatric services and to rotate through the various wards of the neuropsychiatric services in order to gain experience in all phases of neuropsychiatry.

PACIFIC BATTLE CASUALTIES TO BE RETURNED BY END OF YEAR

The War Department recently announced that most of the 3,000 battle casualties still remaining in the Pacific will be returned to the United States within sixty days and all the other transportable casualties by Christmas. The majority will travel on hospital ships and troop transports, but some will return by air. Ten U. S. Army hospital ships, seven formerly part of the twenty-one ship mercy fleet which brought home 86,422 combat sick and wounded from the Atlantic, now are speeding the return of Pacific battle casualties.

Since the first army hospital ship *Acadia* docked with the first battle casualties in June 1943 the Charleston Port of Embarkation, now "port of call" for hospital ships in the Atlantic, has debarked approximately 11,000 since May.

Six of the army hospital ships are converted Liberties; the others are former troopships and cargo and passenger liners. All the ships are staffed by U. S. Army Medical Department personnel and, with the exception of the *Hope*, *Comfort* and *Mercy*, are crewed by merchant marine seamen employed by the Transportation Corps.

TROOPS TO BE VACCINATED AGAINST INFLUENZA

All army troops in the middle Pacific command will be vaccinated against influenza as part of a worldwide campaign by the Surgeon General to prevent a possible epidemic of this disease, in which mass movements of army personnel to and from the continental United States could be a contributing factor. According to Lieut. Col. T. G. Ward, preventive medicine officer, middle Pacific Surgeon's Office, medical officers hope to lessen the severity of any influenza epidemic such as the one which swept the world in November 1918. Millions of army troops, either replacements in occupation armies or combat veterans going home, will be on the move. Through the use of this new vaccine it is hoped to prevent influenza among them.

ARMY AWARDS AND COMMENDATIONS

Major Matthew Levine

The Bronze Star was recently awarded to Major Matthew Levine, formerly of Brooklyn, who served on the Army Hospital Ship *Emily H. M. Wedder* from August 1944 to March 1945. According to the citation accompanying the award Major Levine "demonstrated outstanding professional qualities in support of combat operations. During the invasion of southern France, in the Italian combat zone and later during the landings on Leyte and Luzon in the Philippines this hospital ship participated in the evacuation of wounded from the established beachheads. Aware of the many problems arising from such an important mission, without regard for his personal welfare and with an all consuming zeal for rendering all service possible to our wounded, he skilfully organized the personnel of the Neuropsychiatric Service into a highly efficient unit, inspiring them with confidence in the mission to be performed. His sole aim was to save lives and to bring comfort to the sick and wounded transported aboard the ship. He succeeded in this purpose by utilizing every available means of medical skill and knowledge. His treatment of mentally disturbed patients by neuropsychiatric therapy contributed notably to the successful mission of this ship and reflects great credit on the Medical Corps." Dr. Levine graduated from Long Island College of Medicine, Brooklyn, in 1934 and entered the service July 27, 1942.

Lieutenant Colonel Benjamin L. Camp Jr.

The Legion of Merit was recently awarded to Lieut. Col. Benjamin L. Camp Jr. for his exceptionally successful execution of medical operations connected with the Allied occupation of Rome. He was cited "for exceptionally meritorious conduct in the performance of outstanding service against the enemy in Italy from Feb. 1, 1944 to May 27, 1945. . . . Also for his brilliant conception of medical planning operations and exceptionally successful execution of medical operations connected with the Allied occupation of Rome and the

exceptionally high degree of diplomacy and integrity exhibited which resulted in the optimum of cooperation between Allied and civil medical authorities." Dr. Camp was previously commended by Major Gen. Morrison C. Stayer, surgeon general of the Mediterranean Theater of Operations. This commendation read, in part, "Your problems as surgeon of the Rome Area Allied Command were many and vexing and the manner in which you and your personnel have solved them and safeguarded the lives and health of American troops is worthy of commendation." Dr. Camp graduated from Northwestern University Medical School, Chicago, in 1933 and entered the service Feb. 28, 1941.

Colonel Clifford V. Morgan

The Oak Leaf Cluster to the Legion of Merit was recently awarded to Col. Clifford V. Morgan, formerly of Washington, D. C., "for exceptionally meritorious conduct in the performance of outstanding services as deputy general purchasing agent, Forward Echelon, Headquarters Communications Zone, European Theater of Operations, from Feb. 25, 1944 to Aug. 7, 1944." The citation accompanying the award explained that "Colonel Morgan supervised and coordinated general purchasing planning as far as coordination was necessary with the 21st Army Group (British), First United States Army Group, First United States Army, Third United States Army Western Task Force, 9th Air Force and agencies of the Communications Zone staff. He ably guided and facilitated purchasing planning for overseas operations and formulated a clear and concise general purchasing plan consistent with directives of higher authority. Colonel Morgan rendered outstanding services on the continent not only by advising and personally assisting the Advance Section but also by attaching key personnel to that section for training purposes." Dr. Morgan graduated from the University of Nebraska College of Medicine, Omaha, in 1927 and entered the service July 15, 1927.

Brigadier General Royal Reynolds

Brig. Gen. Royal Reynolds, formerly of Washington, D. C., was recently awarded the Legion of Merit. The citation read "He served as commanding general of the Kennedy General Hospital, Memphis, Tenn., from June 1942 to January 1945. Assuming command when the construction was in its initial phase and when the need for hospital beds for our overseas wounded was most acute, his unusual foresight and planning ability accelerated the building program to such a degree that the necessary hospital facilities with 1,500 beds were in use by Jan. 1, 1943. Authorized to double the capacity in the fall of 1942, construction was begun in October and the new project was in operation by May 1943. A further construction project, instituted late in 1944, increased the bed capacity to 4,387. The rare ability shown by him in providing medical care of the highest quality and unusual efficiency of operation while simultaneously administering his hospital and supervising its growth resulted in a general hospital of outstanding merit." General Reynolds graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1906 and entered the service May 20, 1942.

Lieutenant Colonel Clyde B. Meffert

The Legion of Merit was recently awarded to Lieut. Col. Clyde B. Meffert, formerly of Cedar Rapids, Iowa, "for exceptionally meritorious conduct in the performance of outstanding services as chief of surgical service, 109th Evacuation Hospital, Third U. S. Army, from April 7, 1944 to Jan. 28, 1945. Lieut. Col. Meffert exhibited an unusually high degree of professional skill and exceptional administrative and organizational abilities in the fulfillment of his task. His performance of service made it possible for this organization, with only one week of unit training and two weeks of actual maneuvering, to establish an efficiently functioning hospital. Through Lieutenant Colonel Meffert's untiring efforts this superior surgical service was maintained throughout operations." Dr. Meffert graduated from the State University of Iowa College of Medicine, Iowa City, in 1931 and entered the service June 16, 1943.

Lieutenant Colonel Nevin B. Anderson

Lieut. Col. Nevin B. Anderson, formerly of Des Moines, Iowa, was recently awarded the Legion of Merit for services in North Africa, Italy and France from Sept. 1, 1943 to Dec. 31, 1944. The citation accompanying the award stated that it was given "for exceptionally meritorious conduct in the performance of outstanding services in North Africa, Italy and France from September 1943 to Dec. 31, 1944. Commanding a unit designated for exclusive operation in neuropsychiatry, Lieutenant Colonel Anderson, despite critical shortages of specialists and insufficiencies of suitable facilities, displayed marked ingenuity and efficiency in planning and developing an unprecedented service that paid untold dividends in the treatment of mental cases in two theaters of operation. Utilizing ex-line officers and noncommissioned personnel he provided an occupational therapy program which not only expedited the rehabilitation and restoration of patients but also greatly increased the facilities of his installation. Through the application of sound principles and superior professional skill, Lieutenant Colonel Anderson contributed immeasurably to the success of the combat forces." Dr. Anderson graduated from the State University of Iowa College of Medicine, Iowa City, in 1920 and entered the service Jan. 13, 1941.

Colonel James W. Bass

Col. James W. Bass, formerly of Dallas, Texas, was recently awarded the Legion of Merit for "exceptionally meritorious achievement in the performance of outstanding services in the Southwest Pacific Area, from April 12, 1942 to June 1, 1945. As chief of the Preventive Medicine Section, United States Army Services of Supply, Colonel Bass was responsible for the planning, organizing and supervision of the statistical and preventive medicine program of the theater. Despite formidable problems incident to the medical care of large numbers of men under hazardous and deleterious tropical conditions, he carried a sound and comprehensive program through the formative stage to completion in an exceptionally short period of time. In addition, he developed a department to maintain vital statistics and medical records of inestimable value to the service. As chief inspector, he personally supervised much of the field work of the early operational period and was largely responsible for sanitation measures essential to the maintenance of the present high level of health within the theater. By his professional capability, inspiring leadership and devotion to duty, Colonel Bass has substantially aided in the conservation of manpower throughout the Southwest Pacific Area." Dr. Bass graduated from Baylor University College of Medicine, Dallas, in 1925 and entered the service May 15, 1941.

Captain Rae N. Foster

Capt. Rae N. Foster, formerly of Portland, Ore., was recently awarded the Bronze Star "for meritorious service in connection with military operations against an enemy of the United States during the period June 6, 1944 to May 7, 1945. Captain Foster, serving as an anesthetist with a general surgical team, 4th Auxiliary Surgical Group, distinguished himself by his outstanding performance of duty. The professional skill and untiring energy he displayed, his resourcefulness and loyal devotion to duty reflect great credit on himself and on the military service." Dr. Foster graduated from the College of Medical Evangelists, Loma-Linda, Calif., in 1936 and entered the service July 26, 1941.

Captain Leonard M. Klein

The Bronze Star was recently awarded to Capt. Leonard M. Klein, formerly of Boston. The citation stated that "during the period May 7-May 12, 1945 Captain Klein remained on duty constantly, day and night, at . . . an aid station . . . near Hot Corners, Luzon, Philippine Islands. Because of his untiring efforts and his superior knowledge and skill, Captain Klein was responsible for saving many sick and wounded from long periods of convalescence or possible death. Captain Klein's attention to duty was in accordance with the highest standards of his profession and office." Dr. Klein graduated from Tufts College Medical School, Boston, in 1940 and entered the service Aug. 6, 1942.

Colonel Robert F. Bradish

The Legion of Merit was recently awarded to Col. Robert F. Bradish, formerly of Washington, D. C., who as post surgeon, New Orleans Port of Embarkation, from September 1943 to April 1945, displayed a high degree of organizing and professional ability in establishing and coordinating a highly efficient medical service for both military and civilian personnel within the command, resulting in substantially lowering the noneffective sick rate and in effecting noteworthy reduction in medical operating personnel. The citation accompanying the award goes on to state that "his work in planning, supplying and operating all troop ship hospitals assigned to New Orleans Port of Embarkation and in the evacuation of patients of all categories from overseas areas served by the port was characterized by keen perception of existing conditions and skilful approach to the voluminous problems involved. The resourcefulness, seasoned technical judgment and exceptional professional ability displayed by him contributed materially to the successful operations of the port." Dr. Bradish graduated from the University of Vermont College of Medicine, Burlington, in 1926 and entered the service July 16, 1926.

Captain William T. Layman

The Bronze Star was recently awarded to Capt. William T. Layman, formerly of Hagerstown, Md., "for meritorious service in direct support of combat operations from July 28, 1944 to May 8, 1945 in France, Belgium, Holland and Germany. Although many bridging operations were carried out under observed enemy artillery fire, Captain Layman remained at the

site of operations, rendering immediate aid as battalion surgeon to the wounded. By his tireless efforts, disregard for his own personal safety and fearless devotion to duty, he was an inspiration to the men working under him and reflected much credit on himself and the armed forces." Dr. Layman graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1939 and entered the service May 19, 1942.

Captain James S. Walker

Capt. James S. Walker, formerly of Indianapolis, was recently awarded the Bronze Star for "thirty months' meritorious service with the 46th Engineers, and treating wounded under enemy fire during the landing on Leyte in October 1944." Dr. Walker is now chief of the ear, nose and throat section of the 59th Station Hospital in the Philippines. He graduated from Indiana University School of Medicine, Indianapolis, in 1939 and entered the service Oct. 22, 1941.

Captain Alfred R. Brin

The Certificate of Merit was recently awarded to Capt. Alfred R. Brin, formerly of Terrell, Texas, for "having devoted his time selflessly to duties in an outstanding manner in caring for his many patients during the period from June 1944 to June 1945 in Malmesbury, Wilts, England, resulting in outstanding accomplishments and substantial contributions to the professional field of urology." Dr. Brin graduated from the University of Texas Medical Branch, Galveston, in 1938 and entered the service Sept. 24, 1940.

NAVY**NAVY HOSPITALS FOR ASTHMATIC PATIENTS**

The Bureau of Medicine and Surgery, Navy Department, has allocated a hospital facility devoted in a special manner to the study and care of patients with asthma. The hospital is located in Banning, Calif., and an efficient staff under specialists trained in allergy has been assigned. The area was selected because of environmental conditions conducive to the advancement of patients afflicted with allergic diseases. The high altitude, the equable climate and the low pollen and mold counts make the facilities ideal for a control study of asthma. Over 200 asthmatic patients were recently admitted to the hospital, and preliminary studies have revealed that these patients may be catalogued into three general classes: (1) those whose allergy (asthma) existed prior to enlistment (EPTE), (2) those in whom it did not exist prior to enlistment (DNEPTE) and (3) those whose asthma did not exist prior to enlistment, although a state of hypersensitivity did exist prior to enlistment (EPTE aggravated). Groups 1 and 2 represent 65 per cent and 15 per cent respectively of the patient load, whereas group 3, 20 per cent, represents cases of hypersensitivity prior to enlistment, although no manifestations of asthma were present until after the patient entered the service. Most of the men had seen service overseas, chiefly in New Guinea and in the Philippine, Solomon and Admiralty Islands, and approximately 90 per cent of them had their affliction aggravated by this type of foreign duty.

Although present facilities permit only limited investigation and treatment, more extensive work, particularly regarding offending factors and desensitization studies, are planned for the immediate future.

NAVY AWARDS AND COMMENDATIONS**Commander Stephen Eugene Flynn**

The Bronze Star was recently awarded to Comdr. Stephen Eugene Flynn, formerly of Washington, D. C., "for distinguishing himself by meritorious conduct in the line of his profession while serving as senior medical officer of the U. S. S. *Columbia* during the assault and bombardment operation at Lingayen Gulf, Luzon, Philippine Islands, during Jan. 6-9, 1945. He

administered his department with such excellent foresight that when the *Columbia* was hit by enemy dive bombers January 6 and 9, the large number of casualties which resulted were handled with outstanding efficiency. During the entire period while the ship was under repeated and determined enemy air attacks he worked continuously and tirelessly caring for the wounded and dying. He showed outstanding alertness and initiative by providing, during this trying period with a large number of wounded, for the normal routine of the medical department, even to the extent of performing an emergency appendectomy on the night of January 7. His service and conduct throughout distinguished him among those performing duties of the same character." Dr. Flynn graduated from Creighton University School of Medicine, Omaha, in 1930 and entered the service Dec. 10, 1931.

Lieutenant Max R. Long

The Silver Star was recently awarded to Lieut. Max R. Long, formerly of Indianapolis, "for conspicuous gallantry and intrepidity in action against the enemy as shore party evacuation officer during operations on Saipan. During the morning of June 16, 1944, while the beach from which he was operating was under direct artillery fire, Lieutenant Long, with utter disregard for his own personal safety, continued rendering aid, performing necessary surgery and personally attending to the evacuation of casualties. His efforts, while thus exposed to enemy fire, were a source of inspiration to his own men and a comfort to casualties passing through his hands. Working continuously throughout the first seventy-two hours, he succeeded in evacuating approximately 1,200 wounded men from a heavily congested beach." Dr. Long graduated from Indiana University School of Medicine, Indianapolis, in 1940 and entered the service March 21, 1942.

Lieutenant Commander John W. Stevens

The Navy and Marine Corps Medal was recently awarded to Lieut. Comdr. John W. Stevens, formerly of DuQuoin, Ill., for heroism as battalion surgeon during an aerial bombardment off Roi and Namur in February 1944. The presentation was made in the presence of the entire Georgia Pre-Flight School medical staff, Athens, Ga. Dr. Stevens graduated from the University of Illinois College of Medicine, Chicago, in 1931 and entered the service May 21, 1942.

MISCELLANEOUS

HOSPITALS NEEDING INTERNS
AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service.

(Continuation of list in THE JOURNAL, September 29, page 359)

CONNECTICUT

New Britain General Hospital, New Britain. Capacity, 258; admissions, 8,954. Dr. W. Weston Benjamin, Managing Director (interns; residents—mixed service, April 1, 1946).

MICHIGAN

Saginaw General Hospital, Saginaw. Capacity, 151; admissions, 4,024. Mr. R. E. Raper, Superintendent (interns).

MINNESOTA

Hibbing General Hospital, Hibbing. Capacity, 152; admissions, 3,556. Sister M. Assumpta, Administrator (residents—mixed service).

NEW YORK

Trihora Hospital, Jamaica. Capacity, 557; admissions, 514. Dr. Henry I. Finberg, Medical Superintendent (residents—tuberculosis).
Bronx Hospital, New York City. Capacity, 409; admissions, 10,341. Dr. A. A. Karan, Director (8 interns, April 1, 1946).

OHIO

Lutheran Hospital, Cleveland. Capacity, 160; admissions, 4,525. Mr. Lee S. Lanpher, Superintendent (interns, April 1 and July 1, 1946).

PENNSYLVANIA

Women's Hemoeopathic Hospital, Philadelphia. Capacity, 200; admissions, 3,197. Miss Mary A. Smith, Administrator (resident—male or female).

UNRRA PROGRAM FOR WINTER MEDICAL
CARE IN U. S. OCCUPIED
GERMANY

Health officers of the United Nations Relief and Rehabilitation Administration have recently completed an expanded program of winter medical care for the remaining displaced persons in assembly centers in U. S. occupied Germany. Care will include full scale hospital and dispensary services and an extensive schedule of preventive medicine based on standard public health procedures. The work will go forward under the supervision of the Public Health Branch of the U. S. Military Government. Approximately 500,000 displaced persons are said to be in the U. S. occupied zone at the present time.

Anticipating a severe winter with critical fuel shortages in Germany, UNRRA doctors are immunizing the displaced persons for typhus, diphtheria, typhoid and smallpox. Supplies of the sulfonamide drugs are being stocked for pneumonia. The possibility of typhoid with the spring thaws is also being met now by sanitation measures to check the disease at its sources.

Lieut. Col. David C. Elliott of Cincinnati, chief UNRRA medical officer for the zone, stated that, while it is difficult to forecast accurately the winter health prospects of the displaced persons, reliance has been placed on established health service techniques of preparing in advance for the possibility of critical developments.

UNRRA REPORTS ON THREATENED
TYPHOID EPIDEMIC IN
ALBANIA

Cooperative efforts between authorities in Tirana, Albania, and officials of the United Nations Relief and Rehabilitation Administration broke down a threatened epidemic of typhoid in the capital city of Albania and saved an unknown number of lives. The war had doubled the city's normal population of 40,000 persons, with consequent overcrowding and strain on the city's water and sanitary facilities. When 600 typhoid cases were reported in the outbreak, the Albanian minister of health appealed to Dr. W. E. Thompson of England, UNRRA's director of health attached to its Albanian mission. Dr. Thompson

cabled UNRRA area headquarters at Caserta for emergency shipment of 150,000 units of typhoid vaccine. All available medical personnel were mobilized, and residents of the city were vaccinated by the thousands.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

Illinois

Station Hospital, Camp Grant: Infections of the Hand, Dr. Sumner Koch, November 21.

Regional Hospital, Chanute Field, Rantoul: Traumatic Intracranial Hemorrhage, Dr. Paul C. Bucy, November 14.

Station Hospital, Fort Sheridan: Types of Diabetes Mellitus and Their Treatment, Dr. Arthur R. Colwell, November 14.

Gardiner General Hospital, Chicago: Problems in Returning to Practice in Metropolitan Area, Dr. Francis Strauss, November 7.

Mayo General Hospital, Galesburg: Surgical Treatment of Gastrointestinal Ulcer, Dr. Lester R. Dragstedt, November 21.

Vaughan General Hospital, Hines: A Method for Urologic Diagnosis, Dr. D. K. Rose, November 17.

Indiana

Billings General Hospital, Fort Benjamin Harrison: The Use of Chemotherapeutics and Surgery in Chronic Infections of Bone, Dr. Albert J. Key, November 13.

Tennessee

Kennedy General Hospital, Memphis: Infections Hepatitis, Dr. M. Herbert Barker and Dr. Thomas F. Francis, November 13; Protein Metabolism and Surgical Convalescence, Dr. Robert Elman, November 23.

Washington

Baxter General Hospital, Spokane: Preparation of the Mouth for Immediate Dentures, Major Elmer O. Hinman, November 9; War Deafness, Capt. Robert E. Priest, November 16; Keratitis Caused by Emetine Hydrochloride, Major Everett B. Muir, November 16; Tropical Skin Disease, Capt. William Wolf, November 23.

Wisconsin

Station Hospital, Camp McCoy: The Nutrition of the Recalcitrant Patient, Dr. Robert W. Keeton, November 14; Peptic Ulcer, Dr. Walter L. Palmer, November 28.

Station Hospital, Truxa Field, Madison: The Clinical Significance of Hoarseness, Dr. Paul Holinger, November 7; Diabetes, Dr. Elmer L. Sevringhaus, November 21.

VETERANS

MAGNUSON BECOMES ASSISTANT
TO HAWLEY

Dr. Paul B. Magnuson, Chicago, has accepted a post in Washington as assistant to Major Gen. Paul R. Hawley, Surgeon General of the Veterans Administration. His duties will be connected with a plan to appoint civilian doctors to serve in the Army in the second world war, and whose record indicates that they have been devoted to their duties and service to the soldier.

Dr. Magnuson has taken a leave of absence from his duties at Northwestern University Medical School as professor of bone and joint surgery and will devote his full time during the next few months to this assignment. He is not permanently giving up practice or teaching in the medical school and plans to return to his practice as soon as the organization of veterans' care is well under way. This, as indicated now, should not be more than six months.

ORGANIZATION SECTION

REPORTS OF OFFICERS

NOTE.—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available, be published in advance of the session so as to permit careful consideration and discussion.

(Continued from page 640)

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association:

The following annual report of the Board of Trustees is respectively submitted to the House of Delegates. In this report are covered the activities of various councils and bureaus of the Association during the year 1944 and, because of the lateness of the annual meeting of the House of Delegates, reference will be made to some matters that have received attention of the Board of Trustees during the current year.

Many new problems growing out of the prosecution of World War II have arisen within the last two years.

The working personnel of the Association has been greatly depleted and for many months the total number of employees was more than 200 below normal. An employment quota of 482 was imposed on the Association and for weeks at a time it was not possible to keep even this quota filled. The staffs of Councils and Bureaus were seriously reduced by the assignment of staff members to active duty with the military forces, while a large number of the clerical personnel accepted positions in government service or in industrial plants engaged in the production of war material. A considerable number of new employees served for relatively short periods. At the same time, the demands that were made on practically every department were far larger than in normal times. While the severe restrictions on paper supplies have made it difficult to maintain regular printing schedules and to produce printed material of various kinds that could have been utilized to advantage in various ways, it was also difficult to maintain employment in the printing department.

All employees who were assigned to military duty were assured that their positions would be kept open for them, but it has been practically impossible to secure replacements to serve during the war emergency who might be retained for service after the termination of the war.

Income and Expenditures

The official report of the Treasurer and the Association's auditors are appended as a part of this report of the Board of Trustees.

In 1944, as in the previous year, there was a distinct increase in income from all sources over expenditures. Net income in 1944 was \$933,091.34, exceeding the income of 1943 in the amount of \$214,217.58.

Total wages and salaries for the year 1944 amounted to \$1,255,400.84 as compared with \$1,202,472.14 in 1943. While it was necessary to increase both salaries and wages in 1944, the total expenditure for these purposes would have been much larger had it not been for a serious depletion in the number of employees.

The cost of supplies was considerably larger than in the previous year. Expenditures for various services were also larger than in 1943. Had wages and salaries and the cost of supplies and services been maintained at the normal employment level, the net gain in 1944 would have been radically reduced.

Income from investments in 1944 was \$98,494.04 as compared with \$82,744.08 in 1943. Even though the income from this

source exceeds similar income in 1943 by more than \$15,000, the Board of Trustees encountered great difficulty in finding satisfactory investments. Interest rates have been maintained at lower levels than in previous years, and it seems apparent that low interest rates will be maintained for a long time to come. However, the Board has attempted to keep idle funds invested to the fullest possible advantage, and it is gratifying to note that in spite of the nature of the existing situation with respect to investments and interest rates a larger interest return was realized in the past year.

Income from subscriptions to the Association's publications amounted to the sum of \$1,303,043.68, while in 1943 the subscription income was \$1,235,677.33. Advertising income in 1944 amounted to \$1,707,232.10, while in 1943 the sum realized from this source was \$1,366,659.10. The income from these two sources was unexpectedly large and there can be no assurance that such income can be maintained at the same level in succeeding years.

Expenses involved in the conduct of the work of the Councils, Bureaus and Committees in 1944 amounted to \$459,740.12 as compared to \$432,895.96 in the preceding year.

A new item appearing in the Auditor's Report is that pertaining to the cost of the employees' group annuity plan, initiated in 1944, amounting to \$122,354.47.

The cost of publication of the Association's periodicals was \$1,730,400.70 as compared to \$1,628,969.06 in 1943. There was a slight increase in the costs involved in the maintenance of the building, machinery, type and factory equipment, furniture and office equipment. The excess of costs in 1944 over 1943 resulted from increases in wages and salaries and increased cost of paper supplies, engraving, ink, building expense, insurance and taxes, editorials, news and reporting, first class postage, subscription and advertising commissions, group hospital and life insurance and the employees' annuity plan. Excess of income over 1943 is accounted for almost entirely by unusual increases in receipts from subscriptions and advertising and from income on investments.

Dr. Edward M. Pallette

Dr. Edward M. Pallette represented the California Medical Association in the House of Delegates of the American Medical Association at eight annual sessions. In June 1942 he was elected by the House of Delegates to serve as a member of the Board of Trustees of the Association. Throughout his professional career Dr. Pallette was earnestly and actively interested in the affairs of the county medical society and the state medical association of which he was long a member as well as in the welfare of medical institutions in his state and civic affairs in his own community. He was signally honored on many occasions by assignment by his fellows to the highest posts of service, in all of which he served with fidelity and distinguished efficiency.

Death came suddenly to Dr. Pallette in Chicago on Nov. 16, 1944, where he had come to attend an official meeting of the Board of Trustees.

By his willingness to play his full part in the performance of the duties assigned to the Board, his unfailingly courteous and friendly bearing, his tolerance for the opinions and convictions of others as well as his strict adherence to every principle which he believed to be right, Dr. Pallette won and held the respect and affection of all with whom he was associated during his service as an officer of the Association. He will be long remembered as a good and faithful servant of American medicine.

Appointment of Dr. Robert A. Peers

Dr. Robert A. Peers, a delegate of the California Medical Association, was appointed, in conformity with the provisions of the Constitution and By-Laws, to fill the vacancy on the Board of Trustees created by the death of Dr. Edward M. Pallette. The service of Dr. Peers under this appointment will continue until his successor is elected by the House of Delegates.

Cooperative Medical Advertising Bureau

The Cooperative Medical Advertising Bureau serves thirty-five journals published by constituent medical associations. The Advisory Committee to the Bureau is composed of seven members, four of whom were appointed on nominations submitted to the Board of Trustees by editors of the state medical journals. Those so appointed are Drs. John S. Bouslog, E. M. Shanklin, L. Fernald Foster and Stanley B. Weld. The other members of the Advisory Committee are Dr. Walter E. Vest, Mr. W. C. Braun and Dr. Olin West.

The financial records of the Bureau are kept by the Accounting Department and are subject to examination by the same auditors that audit the accounts of the American Medical Association. The following report of income and expense for 1944 has been so audited:

INCOME	
Commissions earned	\$76,452 02
Cash discounts on \$305,805.77 allowed to advertisers ..	14,611.53
	\$61,840 49
Commissions returned to state journals	46,000 00
	\$15,840 49
Expended in operation of Bureau, as itemized below	15,893 87
Balance due A. M. A. to be deducted from 1945 earnings	\$53 38
EXPENSE	
Amount applicable to 1944 in accordance with statement of Dec. 31, 1943	\$ 522 62
Salaries	9,030.30
Accounting departmental	2,160 00
Other departmental	50 10
Postage	392 23
Telegrams and telephone	355 81
Freight and Express	113 28
Departmental printing	385 36
Travel expense	2,157 49
Conference expense	125 00
Mercantile report service	95 81
Group annuity insurance	272 16
Office supplies	183 64
Miscellaneous and director's sundry expense	50 07
Total expense	\$15,893 87

Commissions earned by the Bureau and the amount returned to cooperating journals were larger in 1944 than in any previous year. Mr. Harold L. Sandberg is director of the Cooperative Medical Advertising Bureau and secretary of the Advisory Committee.

Liaison Office

Early in the war period the Surgeon General of the United States Army established a Liaison Office in the offices of the Association, which was maintained until shortly after VJ day. The first medical officer assigned to this duty was Col. Charles G. Hutter, M. C. U. S. Army, whose recent death was greatly deplored by all who knew him. When Colonel

Hutter was given a new assignment, he was succeeded as Liaison Officer by Lieut. Col. Harold C. Lueth, M. C., A. U. S., who served longest in that capacity. After Colonel Lueth was assigned to duty in the Office of the Surgeon General in Washington, Lieut. Col. Robert D. Bickel, M. C., A. U. S., became Liaison Officer and served until after Japan had surrendered and until the Liaison Office was discontinued. The Board of Trustees desires to record an expression of grateful appreciation to the three splendid medical officers assigned as Liaison Officers for their extremely helpful services and to the Surgeon General of the Army for their assignment and for the maintenance of the Liaison Office. The Board also expresses a very earnest hope that the Office of the Surgeon General realized some benefits from the operations of the Liaison Office, since it has been the desire of the Association to be as helpful as possible to all agencies of the government concerned with the prosecution of the war effort.

The Board of Trustees commends to the House of Delegates and to the Surgeon General the fine services of Col. Charles G. Hutter, Lieut. Col. Harold C. Lueth and Lieut. Col. Robert D. Bickel rendered in accord with the highest traditions of medicine and of the United States Army.

Joint Committee on Physical Fitness

The Joint Committee on Physical Fitness, a committee representing jointly the American Medical Association and the National Committee on Physical Fitness, was authorized by the House of Delegates in June 1944 following a recommendation to the House by the Board of Trustees for the creation of such a group. During the year since its establishment, the committee prepared public statements of policy concerning ways of effecting increased physical fitness. Contacts were made with the governors of the individual states urging the establishment of committees in each state and the development of programs for physical fitness. The Joint Committee on Physical Fitness cooperated with various national agencies interested in the same objectives. Much education of the public was accomplished through published addresses, editorials and the issuance of educational material to the press. The committee cooperated with various organizations which submitted programs for increasing physical fitness, particularly in the field of industry. A conference was held for the establishment of standards of physical fitness for persons of various ages, and work was in progress on the publication of manuals on physical fitness for men and women incorporating these standards.

The Congress of the United States, through failure to appropriate additional funds, brought to an end the work of the National Committee on Physical Fitness. That obviously served to discontinue as well the work of the Joint Committee. Those associated with the Joint Committee have had conferences with representatives of the Athletic Institute and other agencies leading to the ultimate formation of a foundation under voluntary auspices, to be known as the Keep Fit Foundation, which will carry on this work. At the time of their last meeting the secretaries and other officers of the state medical societies discussed the program on physical fitness and volunteered their cooperation. The Board of Trustees desires to recommend that organizations in the individual states cooperate with other agencies in furthering this work.

ADDENDA TO REPORT OF BOARD OF TRUSTEES

Report of the Committee on Scientific Research for 1944

During the year twenty-three applications were received and nineteen new grants were made, amounting in all as paid to \$8,480. Sixteen grants were closed. The work under twenty-five grants made before 1944 is in progress but in several cases delayed or suspended on account of the war. During the year unused balances were refunded in the amount of \$822.

The annual financial statement is presented; also lists of grants closed during the year, of pending grants from earlier years, and of grants made in 1914.

FINANCIAL STATEMENT FOR 1911

Balance, Jan. 1, 1911.	\$18,201.16
Appropriation for 1911	11,700.00
Donation to Hunt Fund	500.00
Refund, grant 573	12.23
Refund, grant 611	53.27
Refund, grant 625	170.71
Refund, grant 649	6.17
Refund, grant 651	11.22
Refund, grant 656	133.08
Refund, grant 669	100.00
	\$33,226.16

GRANTS AND EXPENSES PAID IN 1911

Grant 668, George Ulett	\$ 250.00
Grant 669, Hans Popper	400.00
Grant 670, Wilbur Thomas	300.00
Grant 671, A. M. Inssek	1,000.00
Grant 672, Archie R. Tamm	200.00
Grant 673, Leo Hardt	300.00
Grant 674, David J. Sindweiss and Thomas L. Patterson	750.00
Grant 675, Israel Davidsohn	500.00
Grant 676, Frederick M. Allen	500.00
Grant 677, J. LeRoy Conel (Hunt Fund)	500.00
Grant 678, Herbert S. Kupperman	500.00
Grant 679, Theodor I. Bratard (\$600, held in advance)

Grant 681, W. L. Garrey	500.00
Grant 682, Helen Ingelby	500.00
Grant 683, O. Lloyd Houchlin (\$350, held in advance)	
Grant 684, Rachmil Levine	1,000.00
Grant 685, Daniel Glomset	500.00
Grant 686, H. M. Weaver	250.00
Clinical expense	100.00
	\$ 9,980.00
Balance Dec. 31, 1911	\$21,116.16

Respectfully submitted,

COMMITTEE ON SCIENTIFIC RESEARCH OF
THE AMERICAN MEDICAL ASSOCIATION.

N. W. JONES, Portland, Ore.

Term expires, 1919.

JOHN J. MORTON, Rochester, N. Y.

Term expires, 1918.

E. W. GOODPASTER, Nashville, Tenn.

Term expires, 1917.

LUDWIG HICKSON, Chicago.

Term expires, 1916.

MARTIN H. FISCHER, Cincinnati.

Term expires, 1915.

GRANTS OF COMMITTEE ON SCIENTIFIC RESEARCH

NEW GRANTS—1911

- Grant 668, George Ulett, University of Oregon Medical School, \$250, electroencephalogram in experimental focal brain lesions.
- Grant 669, Hans Popper, Cook County Hospital, Chicago, \$400, study of liver structure in relation to function tests. Refund of \$400 when grant entered the Army.
- Grant 670, Wilbur Thomas, Bowman Gray School of Medicine, \$300, experimental cardiac rupture.
- Grant 671, A. M. Inssek, Medical College of State of Carolina, \$1,000, effect of paralysis on human pyramidal system. See grants 672, 1942, and 655, 1943.
- Grant 672, Archie R. Tamm, University of Oregon Medical School, \$200, acoustic area in cortex of dog.

Grant 673, Leo Hardt, Loyola University Medical School, Chicago, \$300, new gynecology.

Grant 674, David J. Sindweiss and Thomas L. Patterson, Wayne University College of Medicine, \$750, relation of the endocrine glands to nutrition.

Grant 675, Israel Davidsohn, Mount Sinai Hospital, Chicago, \$500, problems of Rh factor.

Grant 676, Frederick M. Allen, New York, \$500, studies on refrigeration surgery and treatment. See grant 657, 1913.

Grant 677, J. LeRoy Conel, Harvard Medical School, \$500, postnatal development of the human cerebral cortex (Charles A. Hunt Fund).

Grant 678, Herbert S. Kupperman, University of Georgia, \$500, pregnancy test.

Grant 679, Theodor I. Bratard, University of Minnesota Medical School, \$600, colored illustrations for article on congenital adrenal hyperplasia.

Grant 680, Wilhelm Rath, University of Vermont College of Medicine, \$500, protective effect of thiamine against the toxic cardiovascular action of epinephrine and sympathin.

Grant 681, W. L. Garrey, Vanderbilt University School of Medicine, \$500, amputation of the heart of vertebrates.

Grant 682, Helen Ingelby, Woman's Medical College of Pennsylvania, \$500, problems of cystic disease and endocrinology of the breast.

Grant 683, O. Lloyd Houchlin, Loyola University Medical School, \$350, vitamin E deficiency in relation to cardiac function.

Grant 684, Rachmil Levine, Michael Reese Hospital, Chicago, \$1,000, secretion and metabolism of progesterone in the human abortion.

Grant 685, Daniel J. Glomset, Des Moines, Iowa, \$500, cardiac conduction. See grant 629, 1912.

Grant 686, H. M. Weaver, Wayne University College of Medicine, \$250, production and treatment of alloxan diabetic coma in rats.

STATUS OF GRANT AIDED WORK

1. GRANTS CLOSED DURING THE YEAR

Grant 181, 1917, Warren O. Nelson, Wayne University College of Medicine, \$200, synthetic androgenic substances. Refund \$15.22. Nelson, Warren O. Renewal of Sperm Formation in Hypophysectomized Rats, *Ann. Re. 73: 18, 1941* (supp.), Responses of the Male Sex Accessory Organs to Androgen in Hypophysectomized and Hypophysectomized Castrated Rats, *ibid.*, p. 75. See grant 656, 1913.

Grant 571, 1940, Joseph J. King, University of Minnesota, \$280, antitoxic effect of tissues on the action of sulfanilamide. Jensen, N. K., and Nelson, M. C. Local Sulfanilamide in Compound Fractures, *Surg., Gynec. & Obst.* 75: 31, 1942.

Grant 591, 1910, Percival Binkley, University of Illinois, \$500, effects of electrolytic lesions in the perigeniculate gray matter of the Macaca mulatta. Binkley, Percival and Davis, I. W. Effects of Lesions of Perigeniculate Gray Matter in the Cat, *Proc. Soc. Exper. Biol. & Med.* 51: 105, 1912, The Syndrome of Obstinate Progression in the Cat, *ibid.* p. 107.

Grant 601, 1941, C. J. Calhoun, University of Illinois College of Medicine, \$100, hysterical metabolism. Refund \$79.62. Calhoun, C. J. The Inhibitory Effect of Oxygen on Starving Pathogenic Bacteria (abstract), *Am. J. Path.* 18: 751, 1912.

Grant 617, 1911, Mary John, University of Maryland College of Medicine, \$500, tests of applicability of feather germ reaction to tumor diagnosis. John, Mary. Feather Germ Reaction to Tissue from Patients with Cancer and Other Conditions, *Arch. Path.* 37: 393, 1911.

Grant 619, 1911, Paul Thomas Young, University of Illinois, \$500, appetite and food preferences in the rat. See grants 611, 1912, and 665, 1913.

Grant 629, 1912, Daniel J. Glomset, Des Moines, Iowa, \$500, cardiac conduction—disturbances of ventricular conduction. See grant 685, 1914. Glomset, Daniel J., Glomset, Anna T. A., and Buge, Richard I. Morphologic Study of the Cardiac Conduction System III Bundle Branch Block, *Am. Heart J.* 24: 318, 1914.

Grant 631, 1912, Leopold R. Ceccedo, Fordham University, \$500, vitamin B deficiency of rats and mice. See grant 663, 1913. Ceccedo, Leopold R., and Loy, John R. Relationship Between Protein Intake and Pyridoxine Deficiency in the Rat: The Role of Tryptophan and Cystine. *J. Nutrition* Proc. 3, No. 1 (March) 1911, Protein Intake and Pyridoxine Deficiency in the Rat, *Arch. Biochem.* 5: 207, 1911.

Grant 615, 1912, Reginald Litz, Peter Bent Brigham Hospital, Boston, \$200, how does hyperthyroidism alter clinically? See grant 651, 1913. Litz, Reginald A. Panoramic View of Thyrotoxicosis, *J. A. M. A.* 125: 917, 1944.

Grant 611, 1912, Paul Thomas Young, University of Illinois, \$500, appetite and food preferences in the rat. See grants 619, 1914 and 665, 1913.

Grant 619, 1912, Arthur H. Smith, Wayne University College of Medicine, Detroit, \$200, metabolism of citric acid. Refund \$6.17. Class, Robert N., and Smith, Arthur H. The Selection as Source of Endogenous Citric Acid, *J. Biol. Chem.* 151: 363, 1913.

Grant 651, 1911, Reginald Litz, Peter Bent Brigham Hospital, Boston, \$100, study of toxic diffuse goiter. See grant 635, 1912. Refund \$11.22.

Grant 655, 1913, Arthur M. Inssek, Medical College of the State of South Carolina, \$300, effect of hemiplegia on the pyramidal tract. See grant 671, 1914. Lassek, A. M. The Human Pyramidal Tract VIII. A Preliminary Investigation of the Effect of Hemiplegia on the Fiber Components of the Pyramids, *J. Neurophysiol. & Exper. Grant 663, 1943 L R Cerecedo, Fordham University, \$600 vitamin B deficiencies in rats and mice. See grant 631, 1941

Grant 666, 1943 Ulrich Friedmann, Jewish Hospital of Brooklyn, \$1500 tetanus toxins. See grants 583, 1940, and 663, 1942

Grant 667, 1943 I M Tarlov, New York Medical College, \$500, regeneration of cauda equina. See grant 634, 1942 Tarlov, I. M Autologous Plasma Clot Suture of Nerves Its Use in Clinical Surgery, *J A M A* 126: 741 (Nov 18) 1944

Report of the Committee on Therapeutic Research

The Committee on Therapeutic Research, a standing committee of the Council on Pharmacy and Chemistry, encourages scientific investigations in the field of therapeutics by providing funds for the prosecution of necessary research

During the year 1944 the committee issued twenty-one new grants A detailed list of these grants, together with a list of publications during 1944 and of unexpended grants made before Jan 1, 1944, are included in this report

During 1944 the following grants were issued

Grant 514 Morton McCutcheon, professor of pathology, University of Pennsylvania School of Medicine, the toxicity of sulfonamides and penicillin and the mechanism of chemotaxis in leukocytes, \$150

Grant 515 Harald G O Holck, associate professor of pharmacology, University of Nebraska School of Medicine, the relationship of sex to drug action, \$200

Grant 516 Nellie Perry Watts Department of Pharmacology, Woman's Medical College of Pennsylvania, methods to prolong the action of local anesthetic drugs, \$250

Grant 517 Harry Beckman, professor of pharmacology, Marquette University School of Medicine, avian malaria, \$250

Grant 518 R H Rigdon, professor of pathology, University of Arkansas School of Medicine, preparation of a movie film showing pathologic changes in a case of malaria, \$125

Grant 519 Gladys R Bucher, Department of Physiology, Woman's Medical College of Pennsylvania, pepsin in the urine, \$200

Grant 521 W F Hamilton, professor of pharmacology and physiology, University of Georgia School of Medicine, to investigate intravascular pressures of unanesthetized animals and man and certain problems in the field of shock and changes in the cardiac recoil curve, \$125

Grant 522 Ward J MacNeal, director of the Laboratories of Bacteriology, New York Post Graduate Medical School and Hospital, bacteriophage phenomena, \$400

Grant 523 Ward J MacNeal, director of the Laboratories of Bacteriology, New York Post Graduate Medical School and Hospital, experimental viridans endocarditis, \$400

Grant 524 Harry E Morton, associate professor of bacteriology, University of Pennsylvania School of Medicine, necessity of bacteriostasis or bactericidal action to prevent infection in an animal body, \$100

Grant 525 Herbert Silvette, assistant professor of pharmacology, University of Virginia Medical School, the effect of low brometric pressures on kidneys previously damaged, either surgically or by drugs, \$250

Grant 526 Walter G Crump Jr, assistant professor of surgery, New York Medical College, and Herbert E Hollander, assistant clinical professor, City Hospital the enzyme factors in the transplantation of fetal or infantile pancreatic tissue in the adult recipient, \$200

Grant 527 Ralph G Janes, assistant professor of anatomy, Wayne University College of Medicine, diabetes mellitus produced by alloxan and its modification by various experimental procedures \$200

Grant 528 Inn J Byrd director of medicine, and Kurt Lange, clinical instructor in medicine, New York Medical College capillary permeability of the meninges in meningitis and meningeism, \$350

Grant 529 Inn J Byrd, director of medicine, and Kurt Lange, clinical instructor in medicine, New York Medical College the effectiveness of physical therapeutic measures in peripheral vascular diseases, \$350

Grant 530 Louis M Palermo, assistant professor of surgery, and Boris Pollock, clinical assistant in surgery, New York Medical College, omental grafts, \$200

Grant 531 Thomas H McGavack, associate professor of medicine, New York Medical College, the absorption of compressed pellets of the steroid hormones, \$400

Grant 532 Thomas H McGavack associate professor of medicine, and Herbert Elias, New York Medical College, insulin and diiodrast clearances in endocrine diseases, \$250

Grant 533 Robert S Teague, associate professor of physiology and pharmacology, University of Alabama School of Medicine the metabolism of diethylstilbestrol and its derivatives, with emphasis on the ratio of absorption to the distribution, fate and excretion of these drugs, \$700

Grant 534 Stephen P Jewett, New York Medical College, the use of immunum chloride in psychiatric disorders \$350

Grant 535 Lloyd D Seager, professor of pharmacology, Woman's Medical College of Pennsylvania, the pharmacology and toxicology of the diuretics, \$400

The following is a list of the investigations conducted with the assistance of grants made by the Committee on Therapeutic Research, reports of which were published during 1944

The Diuretic Effect of Gelatin Solutions C L Bridger, S L Smathers C W Cotterman, J T Damico and J Maxwell Little *Am J Physiol* 142:21 (Sept) 1944

Plasma Retention, Urinary Excretion and Effect on Circulating Total Red Cell Volume of Intravenous Gelatin in Dogs with Diminished Plasma Volume, J Maxwell Little and J T Damico *Am J Physiol* 110:636 (Feb) 1944

Micro Glass Electrode Technique for Determination of Hydrogen Ion Activity of Blood and Other Biologic Fluids, C Lloyd Cliff and Oliver Swenson *J Biol Chem* 152:519 (March) 1944

Growth and Reproduction During Chronic Exposure to Carbon Monoxide, Virginia Suhrie and A T Miller Jr *Proc Soc Exper Biol & Med* 55:85, 1944

Further Studies on the Central Nervous System Action of Benzimidazole HCl, Louis Goodman and Nancy Hunt *Federation Proc* 3:73 (March) 1944

The Diuretic Action of Benzimidazole, Louis Goodman and Nancy Hunt *Federation Proc* 3:73 (March) 1944

The U S P Collaborative Digitalis Study Using Frogs (1939-1941), Lloyd C Miller *J Am Pharm A (scient ed)* 33:245 (Aug) 1944

Influence of Sex on Resistance to Oribanin in the Rat, Harold G O Hulek and Kazuo K Kimura *Federation Proc* 3, March 1944

Effects of Age, Sex, Castration and Interval of Time After Parturition on the Ability of the Albino Rat to Build up Tolerance to and to Detoxify Pentobarbital Sodium, Harold G O Hulek and Donald R Mathieson *J Am Pharm A (scient ed)* 33:174 (June) 1944

Digestive Tract Intraluminal Pressures with Special Reference to Gastrointestinal Propulsion and Gastric Evacuation J P Quigley *Medical Physics (Chicago Year Book Publishers, 1944), p 310*

Application of the "Inductograph" to the Registration of Movements Particularly of Bony Structures Such as the Pyloric Sphincter, D A Brody and J P Quigley *J Lab & Clin Med* 29:863 (Aug) 1944

Reactions Characterizing the Oxide of 6 Methyl-6-oxo-5-chloro-1,5-bis(4-chlorophenyl)-1,3,5-triazine J Am Chem Soc 66:146 (Jan) 1944

The Apparent Advantage of Frequently Administered Quinine in Avian Malaria Infections Harry Beelman and Jane Smith *J Lab & Clin Med* 29:43 (Jan) 1944

The Influence of Diet on Sulfonamide Action, Esther M Greiselman, Robert Hefkesberg and Grace L Weitenberger *Am J Digest Dis* 11:13 (Jan) 1944

Effect of Estrogens on the Testis in Hepatic Insufficiency, Thomas G Morrison *Arch Path* 37:39 (Jan) 1944

Actions of Benzadrine and Propadrine in the Control of Obesity, M L Trinter *J Nutrition* 27:89 (Jan) 1944

Acute Toxicity of Choline Hydrochloride Administered Intravenously to Rats, Harold C Hodge *Proc Soc Exper Biol & Med* 57:26, 1944

Arterial, Cerebrospinal and Venous Pressures in Man During Cough and Strain, W J Hamilton, R A Woodbury and H F Harper Jr *Am J Physiol* 111:42 (March) 1944

The Patterns of the Arterial Pressure Pulse W J Hamilton *Am J Physiol* 111:235 (April) 1944

Intravenous Pycnograms in Normal and Abnormal Pregnancies Deborah C Levy and John P Peters *Am J Obst & Gynec* 16:801 (Dec) 1943

Progressive Experimental Endocarditis Entry Ward J MacNeil Martha Jane Spence and Alice I Slack *Am J Path* 20:95 (Jan) 1944

Progress in the Study of Experimental Endocarditis Ward J MacNeil Martha Jane Spence and Anne Blewins *New York State J Med* 44:601 (March 15) 1944

Clinical Arrest of Bacterial Endocarditis by Bacteriostatic Agents Particularly Penicillin Ward J MacNeil Anne Blewins and Charles A Pondexter *Bull New York Acad Med* 20:415 (July) 1944

Clinical Arrest of Endocarditis Entry by Penicillin, Ward J MacNeil Anne Blewins and Charles A Pondexter *Am Heart J* 28:669 (Nov) 1944

The Effect of Bromide Administered During Embryonic Development on Learning Tests in Rats Ben King Harned, Hughbert C Hamilton and Vera V Cole *Federation Proc* 3:75 (March) 1944

The Effect of the Administration of Sodium Bromide to Pregnant Rats on the Learning Ability of the Offspring III Three Table Test, Hughbert C Hamilton and Ben King Harned *J Psychol* 18:163 (Oct) 1944

The Measurement of Regional Differences in the Arterial Blood Flow in the Skin Arick B Hertzman *Federation Proc* 3:18 (March) 1944

Vascular Reactions to Cold Related to the Early Stages of Immersion Foot Kenneth I Jochem and Arick B Hertzman *Federation Proc* 3:22 (March) 1944

The Effects of Cold on the Blood Vessels of the Skin of the Forearm Kenneth I Jochem and Arick B Hertzman *Federation Proc* 3:22 (March) 1944

The Effects of Methyl Isopropyl Alcohol and of Reflex Thermal Dilatation on the Cutaneous Blood Flow Walter C Randall and Arick B Hertzman *Federation Proc* 3:38 (March) 1944

Effect of Digitalis and Strophantidin on the Denervated Lymph Heart of the Bullfrog (*Rana carolinensis*), Marion A Reid *Federation Proc* 3:38 (March) 1944

The Antidiuretic Action of Morphine and Its Mechanism R C deBolo *J Pharmacol & Exper Therap* 32:74 (Sept) 1944

The following grants were issued before Jan 1, 1944. In some cases the grant has expired and an unexpended balance remains, or the work is not yet completed, or not yet published

Grant 232 George R Cowgill, associate professor of physiologic chemistry, Yale University School of Medicine, the heart in vitamin B deficiency, \$250

Grant 297 Melvin Dieckbach, Harvard University School of Medicine, the emetic effect of some of the digitals bodies, \$250

Grant 306 Edwards A Park, professor of pediatrics, Johns Hopkins University School of Medicine, rickets in the rat and the effect of solution of parathyroid on the circulation of the bone, \$75

Grant 355 Peter K Knoefel, professor of pharmacology, University of Louisville School of Medicine, the action of amines of the epinephrine series and of related substances on the central nervous system, \$150

Grant 408 Ephraim Shorr, associate professor of medicine, Cornell University Medical College, the effect of progesterone on the vaginal smear, \$300

Grant 412 Anne Imbes, Massachusetts General Hospital, Boston, the effect of various endocrine diseases and the administration of various endocrine products on the 17 β -steroid secretion in the urine, \$400

Grant 410 J P Simonds, department of pathology, Northwestern University Medical School, the selective action of different types of poisons on the kidneys, \$100

Grant 443 A B Baker, associate professor of neuropsychiatry and neuropathology and Raymond N Bicer, professor of pharmacology, University of Minnesota Medical School, toxic effects of sulfamyls and derivatives on nervous system and effect of vitamin B complex in prevention of such injuries, \$500

Grant 445 Paul I Dry, professor of physiologic chemistry, and John R Tatter, instructor in physiologic chemistry, University of Arkansas School of Medicine, ocular manifestations of tryptophan deficiency, \$300

Grant 449 Arick B Hertzman, professor of physiology, St. Louis University School of Medicine, peripheral circulation, \$500

Grant 505 James Orten, assistant professor of physiologic chemistry, Wayne University College of Medicine, to investigate the relationship of dietary protein to porphyrin metabolism in the rat, \$250

Grant 506 Andrew I Burton, assistant professor of pharmacology, Howard University, to investigate (1) the distribution of sulfamyls in maternal and fetal tissues at various stages of pregnancy, (2) the toxic effects of quinine on the fetus in vitro, \$600

Grant 509 Thomas H McGavack, associate professor of medicine, New York Medical College, to investigate water balance under the influence of various hormones, \$350

Grant 510 Louis S Goodman, chairman, department of pharmacology and physiology, University of Vermont College of Medicine, to investigate benzimidazole in comparison with other central nervous system depressants, \$800

Grant 511 K A C Elliott, Chemical Research Laboratory, the Institute of the Pennsylvania Hospital, to investigate the effects of low and high oxygen tensions on brain metabolism, \$500

Grant 512 Isaac White Chin, associate professor of chemistry, University of Denver, the effect of sulfonamide drugs on the glycogen content of the liver of rabbits and rats, \$200

Grant 513 Ruth I Miller, professor of bacteriology, Woman's Medical College of Pennsylvania, to investigate the relationship between immune mechanisms and bacterial resistance, \$412.50

Grant 454 Frederick H Pratt, professor of physiology, and Marion A Reid, instructor in physiology, Boston University School of Medicine, the effect of cardiac drugs on the denervated lymphatic hearts, \$100

Grant 457 Edmund Wynne, associate professor of physiology, Boston University School of Medicine, the factors controlling the growth and functional efficiency of transplanted adrenal cortical tissue, \$72.50

Grant 458 George Lahr, professor of internal medicine, University of Minnesota, the effects of Isonitroide C on certain types of heart disease, \$100

Grant 459 Mary F O Sullivan, Bellevue Hospital, New York City, the therapeutic effect of estradiol in muscular dystrophy, \$160

Grant 472 Robert V Brown, professor of physiology and pharmacology, the University of North Dakota, action of pituitary on bile secretion, \$150

Grant 473 Richard C deBolo, associate professor of pharmacology, New York University College of Medicine, temporary and permanent effects of insulin on carbohydrate metabolism with special reference to its effects on adrenalin hyperglycemia and liver glycogen, \$100

Grant 474: Arthur C. DeGraff, professor of therapeutics, New York University College of Medicine, the effectiveness of sodium thiosulfate and sodium formaldehyde sulfoxalate in treatment of cardiac arrhythmias induced experimentally by mercurial diuretics, \$400.

Grant 477: Harold C. Hodge, associate professor of biochemistry and pharmacology, University of Rochester School of Medicine and Dentistry, acute toxicity of choline, \$200.

Grant 478: Stacy R. Mettier, associate professor of medicine, University of California Medical School, the rH factor in blood transfusion and other immunologic aspects of blood grouping, \$400.

Grant 479: Mayo H. Soley, associate professor of medicine, University of California Medical School, treatment of patients with toxic diffuse goiter by means of radioactive iodine, \$350.

Grant 483: Donald Slaughter, professor of pharmacology and physiology, Southwestern College of Medicine, to investigate the effects of sulfonamides on the regeneration of visual purple, \$150.

Grant 484: Alfred Goerner, associate professor of biologic chemistry, Long Island College of Medicine, and M. Margaret Goerner, pathologist, Brooklyn Thoracic Hospital, the toxic action of carcinogenic compounds on liver tissue, \$400.

Grant 488: L. R. Kaufman, director of surgery, New York Medical College, circulatory competence of the gut in cases of intestinal obstruction, \$125.

Grant 489: L. R. Kaufman, director of surgery, New York Medical College, the use of enzyme mixture for dissolving slough, \$100.

Grant 490: Andrew F. Burton, assistant professor of pharmacology, Howard University School of Medicine, the distribution of sulfanilamide and the toxic effects of quinine, \$698.

Grant 491: Fred D. Weidman, professor of dermatology and vice dean for dermatology and syphilology, University of Pennsylvania Graduate School of Medicine, the control of dermatophytosis and value of living *Bacillus subtilis* cells, \$500.

Grant 494: Amedeo S. Marrazzi, professor of pharmacology, Loyola University School of Medicine, to investigate sympathomimetic amines, \$500.

Grant 497: E. Ross Hart, associate professor of pharmacology, Jefferson Medical College of Philadelphia, to investigate the pharmacologic properties of N-allyl-nor-morphine and related compounds, \$250.

Grant 498: Linn J. Boyd, director of medicine, and Kurt Lange, clinical instructor in medicine, New York Medical College, to investigate the effect of cold in the treatment of shock, \$300.

Grant 499: Joseph Litwins, clinical instructor in medicine, New York Medical College, to investigate the chemistry and hematology of blood donors, \$200.

Grant 502: Julian P. Macs, department of pharmacology, Dartmouth College, to investigate the part played by the red blood corpuscle concentration of the systemic circulation in the maintenance of blood pressure at different levels of vasoconstrictor tone, \$150.

TREASURER'S REPORT

Report of the Treasurer of the American Medical Association for the Year Ended December 31, 1944

Investments (At Cost) as at January 1, 1944.....	\$3,258,131.33
Bonds Purchased (At Cost).....	1,666,103.99
	<u>\$4,924,235.32</u>
Less:	
Bonds Called, Matured or Sold.....	327,384.85
	<u>Investments as at December 31, 1944.....</u>
	\$4,596,850.47
Balance for Investment January 1, 1944.....	207,900.01
Interest Received on Investments Year 1944..	102,906.10
	<u>310,806.11</u>
Bonds Purchased (At Cost plus Accrued Interest \$1,013.78)	243,740.25
	<u>Uninvested Funds December 31, 1944....</u>
	67,065.86
Invested and Uninvested Funds as at December 31, 1944...	<u>\$4,663,916.33</u>

DAVIS MEMORIAL FUND

Balance in Fund January 1, 1944.....	\$7,709.49
Interest Earned on Bank Balance Year 1944.....	96.66
	<u>Funds on Deposit as at December 31, 1944.....</u>
	\$7,806.15

JOSIAH J. MOORE, M.D., Treasurer.

AUDITOR'S REPORT

January 30, 1945.

To the Board of Trustees,
American Medical Association, Chicago, Illinois.

Dear Sirs:

We have examined the balance sheet of the American Medical Association, Chicago, Illinois, as of December 31, 1944, and the statement of income for the year ended on that date, have reviewed the system of internal control and the accounting procedures of the Association and, without making a detailed audit of the transactions, have examined or tested accounting records and other supporting evidence, by methods and to the extent we deemed appropriate except as hereinafter stated regarding confirmation of receivables and observation of the inventory taking.

The cash and bank balances have been confirmed by count or by certificates from the depositaries. The United States Government and other marketable securities were confirmed by an acknowledgment from the Continental Illinois National Bank and Trust Company of Chicago where the securities are held for safekeeping.

We did not independently confirm the accounts receivable by communication with the debtors. The accounts receivable were reviewed as to age and collectibility and, in our opinion, the balances are fully realizable. We reviewed the plan and system of control adopted for inventory taking but we did not observe the taking of the inventories nor did we make tests of the physical existence of the quantities recorded.

Expenditures charged to property and equipment accounts during the year, in our opinion, were properly capitalized as representing additions or improvements. The provision for depreciation for the year appears to be adequate.

In our opinion, subject to the exceptions set forth in paragraph three, the accompanying balance sheet and related statement of income present fairly the position of the American Medical Association at December 31, 1944, and the results of the operations for the year, based on the accounting procedures employed by the Association regarding which the following observations are submitted:

(a) In accordance with the established practice of the Association, the accounts as stated do not include (a) unrecorded assets in respect of accrued interest on bond investments, and membership dues unpaid; and (b) provision for accrued property taxes for the year 1944, and sundry unpaid bills and wages.

(b) Subscriptions paid in advance are stated at an estimated amount which is based on cash received in December 1944, on account of 1945 subscriptions. This procedure conforms to the method used in prior years.

(c) Advance payments on publications include an estimated amount (\$167,108.36) for prepaid subscriptions to *Hygeia*, and the amount (\$78,065.95) received in advance for January 1945, advertising, directory information sales and service.

We have received a letter from Messrs. Loesch, Scofield, Loesch and Burke, attorneys for the Association, regarding litigation pending against the Association or its officers at December 31, 1944, which states that the case of Jean Paul Fernel (\$1,000,000—libel) is pending and that in their opinion this suit will be defeated.

Fidelity insurance is carried against the undermentioned officers and employees, in the amounts stated:

Dr. Olin West, Secretary and General Manager.....	\$10,000.00
Dr. Joseph J. Moore, Treasurer.....	10,000.00
E. A. Hoffman, Cashier.....	10,000.00
J. E. Hartigan, Assistant Cashier.....	2,000.00
Hiley Ward, Accountant.....	2,000.00
Sundry employees (sixteen, \$1,000.00 each).....	16,000.00

Total Fidelity Insurance.....\$50,000.00

We have pleasure in reporting that the books are well maintained and that every facility was afforded us for the proper conduct of the examination.

Yours truly,

PEAT, MARWICK, MITCHELL & CO.

Discounts	67,012.28
Exchange	1,718.22
Subscription promotion expense.....	21,236.59
Office supplies	7,860.58
Telephone and telegrams.....	4,247.35
Office printing	27,173.24
Binding	2,969.45
Miscellaneous operating expenses.....	23,317.57
Group hospital and life insurance.....	9,136.19
Loss (profit) bad debts and recoveries—net.....	413.7
Loss on metal dress sales.....	611.61
	<u>1,713,724.62</u>
Depreciation (based on estimated remaining life):	
Buildings	\$23,133.80
Machinery	13,768.50
Type and factory equipment.....	1,340.47
Furniture and equipment.....	7,411.00
	<u>45,753.77</u>
	<u>1,759,478.39</u>
Deduct—Proportion of overhead expenses charged to other publications and departments.....	29,226.69
Total Publications (Periodicals)—Costs and Expenses.....	<u>\$1,730,400.70</u>

Note: Total wages and salaries for year 1944 amounted to \$1,255,460.84. Of this amount, \$826,518.54 is included above. \$294,932.67 is shown in Schedule "2" (expenses of Councils, Bureaus and Committees), and the remainder, \$133,943.63, was disbursed on the maintenance of records which will be used in connection with the next edition of the American Medical Directory, and with the printing of books, reprints and pamphlets, and printing in process at the close of the year.

SCHEDULE "2"

EXPENSES OF COUNCILS, BUREAUS AND COMMITTEES

FOR THE YEAR ENDED DECEMBER 31, 1944

Salaries and wages.....	\$294,938.67
Office printing	13,287.75
Office supplies and repairs.....	6,108.40
Express, telephone and telegraph.....	5,801.96
Postage	7,791.51
Binding	577.10
Books and periodical subscriptions.....	869.87
Educational material distributed.....	5,732.09

NOTE: The above expenses are spread over the following Councils, Bureaus and Committees as indicated: Association account, \$109,719.25; Bureau of Health Education, \$50,974.25; Council on Pharmacy and Chemistry, \$43,694.23; Chemical Laboratory, \$16,997.47; Council on Physical Medicine, \$18,917.60; Council on Foods, \$17,158.30; Committee on Therapeutic Research, \$6,486.05; Council on Medical Education and Hospitals, \$58,081.61; Bureau of Legal Medicine and Legislation, \$30,723.00; Bureau of Investigation, \$9,144.31; Bureau of Medical Economics, \$17,557.30; Council on Industrial Health, \$22,540.98; Association and Bureau of Exhibits, \$18,734.59; Council on Medical Service and Public Relations, \$28,712.71; Committee on Medical Preparedness, \$9,698.47.

REPORT OF THE COUNCIL ON
SCIENTIFIC ASSEMBLY

To the Members of the House of Delegates of the American Medical Association:

Because of the enforced cancellation of the annual session for 1945, the Council on Scientific Assembly has little else to report except that the usual Annual Conference of the Council with the Section Secretaries was held late in 1944. At that conference plans were made for the scientific program for 1945. Considerable progress had been made in the preparation of the section programs and the program for the General Scientific Meetings. The Council desires to express appreciation of the services of officers of the scientific sections and its regret that their efforts toward the preparation and presentation of good programs were made futile by the cancellation of the annual session.

The House of Delegates in 1941, after giving consideration to a resolution submitted by Dr. Henry A. Luee, delegate from Michigan, proposing that a Section for General Practitioners be established in the Scientific Assembly, requested the Council to arrange for Sessions for General Practitioners in the Section on Miscellaneous Topics, and this was done in 1942 and in 1944. The programs presented at those sessions attracted a rather large attendance, and the manner in which they were received seemed to indicate that there was a real desire for the establishment of a Section for General Practitioners. The Council on Scientific Assembly therefore recommends to the House of Delegates that such a section be established and that proper amendment be made to the By-Laws to include the new section.

Respectfully submitted,

A. A. WALKER, Chairman.

FREDERICK A. COLLIER.

CLYDE L. CUMNER.

EDWARD L. BORTZ.

CHARLES H. PHIFER.

ROGER I. LEE, President-Elect.

MORRIS FISHBEIN, Editor, THE JOURNAL

OLIN WEST, Secretary.

Ex officio.

Washington Letter

(From a Special Correspondent)

Oct. 29, 1945.

Approval of National Research Foundation by
American Medical Association

A statement of Dr. Morris Fishbein, Editor of THE JOURNAL, to the joint subcommittee of the Senate Commerce and Military Affairs Committees expressed approval by the American Medical Association of the proposal to set up a National Research Foundation. Dr. Fishbein pointed out that the work of the Office of Scientific Research and Development during the war had demonstrated that federal funds could be used satisfactorily to promote research and speed medical discoveries. He warned that the foundation must avoid "bureaucratic domination of research," restrictions on research or undue support in any one field. He also opposed inclusion of social sciences in the federal program, contending that findings might be used to affect legislation and influence political opinion. The committee also heard Howland H. Sargeant, patent chief in the office of the Alien Property Custodian, ask for congressional action to prevent enemy owners from capitalizing on patents.

Controversy Over Use of Influenza Vaccine by Army

A controversy is reported between medical services here over use by the Army of a new influenza serum to vaccinate all its personnel. The navy declares that the vaccine is an "experiment" and the Public Health Service has refused to license it. The Office of the Surgeon General of the Army, nevertheless, is reported to be proceeding with plans for vaccination of every man and woman in the service at home and abroad in the belief that it will prevent an epidemic. Capt. Otto L. Burton, chief of the Navy division of preventive medicine, has stated that "nobody knows what it will do or how long it will immunize." The Public Health Service reported that commercial houses have applied for the right to manufacture the new serum but that the government has declined to license it for public use.

Need for More Psychiatrists

Dr. Karl Menninger, director of the Menninger Clinic, Topeka, Kan., told the National Health Advisory Committee of the National Federation of Business and Professional Women's Clubs that there is a high incidence of mental disease among women and stressed the need for more psychiatrists. Taking part in the program were Dr. Thomas Parran, Surgeon General of the U. S. Public Health Service; Norman Damon of the Automotive Safety Foundation; Dr. Dorothy Nyswander, consultant in health education, Inter-American Educational Foundation, and Miss Melva Bakkie, director, Nutrition Service, American Red Cross.

Health Needs of School Age Children

A report by the Health and Physical Education Service, U. S. Office of Education, states that the health and fitness needs of school children are not being met. It contends that a community health program can be more easily and efficiently carried out while the student is in school. Health activities within the school are listed as examination, immunization and follow-up leading to corrective services, plus provision for a safe, sanitary and healthful school environment.

Plans for Disposal of Surplus Property Relating
to Health

Dr. J. O. Dean of the U. S. Public Health Service was to testify on plans for disposal of surplus property relating to health, before the Kelley Subcommittee on Aid to the Physically Handicapped. Dr. H. D. Alves of the U. S. Office of Education was also authorized to describe plans for disposal of surplus educational materials. They were delegated by the Surplus Property Director to appear for him.

President's Physician to Teach in Washington

Col. Wallace Graham, appointed recently as personal physician to President Truman, is expected to join the instructional staffs of two Washington medical schools. He is already on the staff of Walter Reed Hospital.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ARKANSAS

District Meeting.—The Fifth District Medical Society was addressed in Camden October 16 by:

Capt. Horace R. Boone (MC), Memphis, Rehabilitation of the Navy Patient.

Dr. Jacob Alperin, Memphis, Tenn., Harmful Effects of Morphine and Digitalis in Heart Disease.

Dr. Robert L. Sanders, Memphis, Tenn., The Diagnosis and Management of Obstructive Lesions of the Colon.

Vice Admiral Ross T. McIntire (MC), Medical Research in War and Peace.

At an evening public session the speakers included Governor Ben T. Laney, Arkansas, and Dr. McIntire on "War Medicine and Its Future Impact."

CALIFORNIA

County Society Considers New Home.—Members of the San Francisco County Medical Society will soon vote on the disposition of its headquarters at 2180 Washington Street, San Francisco, and the consideration of a new home. The bulletin of the society for October discusses the various aspects of the project which will be presented to the membership for vote.

School Teacher Named to Psychiatric Staff.—Miss Grace Ahrens, a school teacher, has been appointed to the staff of the child psychiatry unit of the Langley Porter Clinic of the University of California Medical School, San Francisco. The school program will be conducted for five hours each day and is being integrated with the other treatment given the mentally sick children. The school will form an important part of the treatment, since many of the children have been referred to the clinic because of behavior or other difficulties in school. With some children the school has come to be associated with painful experiences so that almost all learning is blocked, but as the child gradually reaches a better mental adjustment he also learns to accept the school situation. Some text books and the same type of treatment carried on in public schools will be used.

Funds for Tuberculosis Library.—The B. P. O. Elks Lodge Number 99 of Los Angeles has given \$12,000 to the Barlow Sanatorium of Los Angeles to establish a library for research in tuberculosis. According to Dr. Howard W. Bosworth, medical director of the Barlow Sanatorium Association, this fund is intended to finance the erection of a small building and the purchase of furniture and equipment, books and medical journal subscriptions. It is hoped to build up as complete a library as possible in the field of tuberculosis and diseases of the chest. This library will be designed to serve the staff of the sanatorium, the teaching of student nurses in tuberculosis, teaching of medical students from the University of Southern California in tuberculosis, postgraduate courses for physicians in tuberculosis, and physicians or other persons in this area seriously interested in tuberculosis. The reading room of the library will be designed for use as a class room for staff meetings, committee meetings and lectures. It will be known as the Elks' Tuberculosis Library of the Barlow Sanatorium.

COLORADO

Faculty Changes at Colorado.—The following changes in status of members of the faculty at the University of Colorado School of Medicine, Denver, were recently announced: Dr. John W. Ames, professor of clinical pediatrics emeritus, and John M. Barney, professor of medicine emeritus, both effective September 1. Dr. Arthur J. Markley was also recently made professor of dermatology emeritus. Dr. Osgood S. Philpott was recently appointed professor and head of the department of dermatology. Other changes on the faculty include the appointments at the medical school of Dr. Robert S. Liggett as assistant professor of medicine and assistant dean and Dr. Emmett A. Mechler as assistant professor of obstetrics and gynecology.

ILLINOIS

Personal.—Dr. William F. Schroeder, Rock Island, has resigned as a member of the board of the Rock Island Chamber of Commerce because he has gone to live in California. —Dr. Sander Horwitz, district health officer, who has practiced medicine in Peoria for fifty years, was made a member of the "fifty year club" of the Illinois State Medical Society, September 18. —Dr. Leslie W. Roth, Belleville, formerly assistant professor in the department of physiology and pharmacology of the University of Colorado School of Medicine, Denver, has become research pharmacologist in the department of pharmacology, Abbott Laboratories, North Chicago.

Chicago

Dr. Keefer Discusses Penicillin.—Dr. Chester S. Keefer, Wade professor of medicine, Boston University School of Medicine, spoke on penicillin at a joint meeting of the Institute of Medicine of Chicago and the Chicago Society of Internal Medicine on Friday evening October 26.

Pigeons to Be Tested for Disease.—The laboratory of the state department of health in Chicago will carry on tests of pigeons found near county institutions in an effort to determine the extent of disease that they may carry. Blood tests of 200 pigeons have shown positive reactions of pneumonia type virus in about forty per cent of the birds. Positive reaction to psittacosis was shown in a large number of birds. New tests are being made to establish whether the reaction was caused by present or past infection and whether the birds are carriers of the disease. Final results of tests will be submitted to Dr. Roland R. Cross, Springfield, state director of health, for a decision as to what will be done with regard to eliminating pigeon flocks in Chicago.

MARYLAND

Distribution of Medical Care.—The Baltimore City Medical Society and the National Physicians Committee for the Extension of Medical Service cooperated in a program on the distribution of medical care, October 5. The speakers were:

Dr. Dean Robert, Baltimore, chief, Bureau of Medical Services, Maryland Department of Public Health, The Medical Care Program in Maryland.

Dr. Thomas A. McGoldrick, Brooklyn, trustee of the National Physicians Committee and Delegate to the American Medical Association (subject not announced).

Mr. Edward E. Stegen, associate administrator, National Physicians Committee, Reville for Medicine.

MASSACHUSETTS

X-Ray Anniversary Celebration.—The New England Roentgen Ray Society will observe the fiftieth anniversary of the discovery of x-rays November 16 at the Harvard Club, Boston. Among the speakers on the program will be:

Dr. William J. Elliott, Worcester, The Use of X-Rays in Art.

Dr. Paul E. Tivnan, Beverly, Some Industrial Applications of X-Rays.

Joseph T. Walker, Ph.D., Boston, The Application of X-Rays to Crime Detection.

Bertram E. Warren, Sc.D., Cambridge, X-Rays as a Tool of the Physicist.

Dr. Merrill C. Sosman, Boston, X-Rays in Medicine.

MICHIGAN

Institute of Industrial Health.—The Detroit Industrial Safety Council will sponsor an institute of industrial health, hygiene and nursing at the Rackham Building, Detroit, November 6-7 in conjunction with the Michigan Association of Industrial Physicians and Surgeons, Michigan Department of Health, Michigan State Medical Society, Michigan Industrial Hygiene Association, Detroit Department of Health, Wayne County Medical Society and the Detroit Industrial Nurses Association. The speakers will include:

Gordon C. Harrold, Ph.D., Detroit, DDT and Its Mixtures.

William Fredrick, Sc.D., Detroit, Soldering and Brazing Health Problems.

Marguerite F. Hall, Ph.D., Ann Arbor, Application of Public Health Statistical Methods of Health and Safety in the Factory.

Dr. Thomas Francis Jr., Ann Arbor, Upper Respiratory Infections.

Harry E. Miller, B.S., Ann Arbor, Application of Sanitary Engineering Principles to Industrial Health and Safety.

Don D. Irish, Ph.D., Midland, Volatile Solvents in Industry.

Dr. John W. Hirschfeld, Detroit, The Place of Chemotherapy in the Treatment of Traumatic Wounds.

Dr. Frank T. McCormick, Detroit, Surgical Drainage.

One session will be devoted to a symposium on heart disease as related to occupation and one on low back pain.

MINNESOTA

Association of Coroners.—The Minnesota Association of Coroners elected Dr. John W. Ekblad, Duluth, president of the organization at their annual meeting in St. Paul recently. Drs. Edwin A. Kilbride, Worthington, was made first vice president, Reino H. Puumala, Cloquet, second vice president and Russell R. Heim, Minneapolis, secretary-treasurer.

Illegal Practitioner.—Godfried Fruitiger, chiropractor, Wilton Junction, Iowa, was arrested July 25 at Pine Island for practicing healing without a basic science certificate. On July 26 he pleaded guilty to a charge of violating the basic science law and was sentenced to six months in the county jail. Sentence was stayed on condition that Fruitiger refrain from practicing healing in Minnesota. Fruitiger was practicing in a trailer at Pine Island and admitted having treated 12 patients before he was arrested. He made no direct charge for service, but patients left a "gift" of \$1.

Course in Pediatrics.—The University of Minnesota Medical School, Minneapolis, announces the first of a series of continuation courses in pediatrics for pediatricians November 7-10. Faculty for the first course will include:

Dr. Irvine McQuarrie, Minneapolis, University of Minnesota Medical School.

Dr. Henry F. Helmbold Jr., Rochester, Mayo Foundation.

Dr. Helen B. Taussig, Baltimore, Johns Hopkins University School of Medicine.

Dr. Hugh McCulloch, St. Louis, Washington University School of Medicine.

Dr. Milton J. E. Senn, New York, Cornell University Medical College.

Dr. Charles A. Aldrich, Rochester, Mayo Foundation

Subjects to be covered include Convulsive Disorders, Child Psychiatry, Psychologic Measurement, Speech Problems, Psychosomatic Pediatrics, Physical and Mental Development, Congenital Heart Disease, Rheumatic State and Acquired Heart Disease.

MONTANA

Hospital News.—The Gallatin County Medical Association has given about \$15,000 to the campaign for funds to build, an addition to the Bozeman Deaconess Hospital; according to *Montana Health* \$51,000 has been received for the addition.

Personal.—Curtis H. Waldon, Ph.D., formerly professor of pharmacology at Purdue University School of Pharmacy, has been appointed dean of the Montana State University School of Pharmacy, Missoula, to succeed Charles E. Mollett, Ph.C., who has been associated with the school since 1907, both as professor and as dean.

Tuberculosis Officers Reelected.—Dr. E. Martin Larson, Great Falls, was reelected president of the Montana Tuberculosis Association at its twenty-ninth annual meeting in Helena September 8. Other officers who were reelected include Alex Cunningham, Helena, first vice president; Dr. Paul L. Eneboe, Bozeman, second vice president; L. S. Hazard, Helena, treasurer, and Mrs. Henrietta Crockett, Helena, executive secretary.

NEBRASKA

School Radio Health Series Opens.—First of the series of school health transcriptions recently contributed to the Omaha Public Schools by the Douglas County Medical Society was heard over KOWH September 11. The transcriptions, in a series of twelve to be broadcast weekly, are made by the American Medical Association. Title of the first was "Randy Makes Good," listing reasons for good health habits. Pictured at the presentation of the transcriptions are W. H. Waite, director of curriculum, Omaha Public Schools; Dr. Herman M. Jahr, Omaha; Fred Hill, assistant to the superintendent of schools; Dr. Charles W. M. Poynter, dean of the University of Nebraska College of Medicine, Omaha; Dr. Ernest T. Manning, Omaha, director of school health services, and Dr. W. W. Bauer, Chicago, Director of the Bureau of Health Education, American Medical Association.

NEW YORK

Frank Sutton Heads Rochester Hospital.—Dr. Frank C. Sutton, assistant director of the Rochester General Hospital, has been appointed acting medical director. He will take the place of Dr. Christopher G. Parnall, Rochester, who retired September 30 after serving as medical director for twenty years. Dr. Sutton graduated at Northwestern University Medical School, Chicago, in 1938. He has been Dr. Parnall's assistant for the past three years. Dr. John E. Gillick, New York, chief resident physician, will serve as administrative assistant. Dr. Parnall will devote full time to consultation service in hospital construction.

State Medical Election—National Casualty Company Urged.—Dr. William Hale, Utica, was chosen president-elect of the Medical Society of the State of New York at the annual meeting of the house of delegates in Buffalo October 9. Dr. Edward R. Cumiffe, New York, is president. Other officers include Dr. Stephen R. Monteith, Nyack, second vice president; Dr. Walter P. Anderson, New York, secretary; Dr. W. Guernsey Frey, New York, assistant secretary; Dr. Kirby Dwight, New York, treasurer, and Dr. James R. Reuling, Bay-side, assistant treasurer. A resolution was adopted urging an organization of a national casualty company to develop and promote voluntary medical insurance coverage in areas where none exists. The resolution stated that such a casualty company was necessary as an agency to relate the enrolment of nationwide employers to the various local nonprofit plans and can be organized wholly within the control of the medical profession.

New York City

Personal.—Ivan C. Hall, Ph.D., has resigned as professor and director of the department of bacteriology at New York Medical College, Flower and Fifth Avenue Hospitals, New York. *THE JOURNAL*, September 1, page 82, incorrectly reported that Dr. Hall was resigning from the New York University College of Medicine.

The Janeway Lectures.—Henrik Dam, D.Sc., associate member of the Rockefeller Institute for Medical Research, delivered the Edward Gamaliel Janeway Lectures at the Mount Sinai Hospital of New York, October 30-31. His subjects were "Medical Aspects of Vitamin K" and "Some Effects of Vitamin E Deficiency and Fatty Acids."

The Harvey Lecture.—Dr. Alfred Blalock, professor and director of the department of surgery, Johns Hopkins University School of Medicine, Baltimore, will deliver the second Harvey Lecture November 15 at the New York Academy of Medicine. The lecture, which will be on "Physiopathology and Surgical Treatment of Congenital Cardiovascular Defects," is the second in the series sponsored by the Harvey Society and the New York Academy of Medicine.

Conference on Chronic Pulmonary Diseases.—The thirty-fifth clinical session on chronic pulmonary diseases of the Tuberculosis Sanatorium Conference of Metropolitan New York will be held at the Cornell University Medical College Amphitheater, November 7, according to the New York Tuberculosis and Health Association. The program will include papers by Dr. Sol Roy Rosenthal, Chicago, on "Ten Years' Experience with BCG (Clinical and Experimental)" and Dr. Milton I. Levine, New York, "The Results of BCG Inoculation of Children from Tuberculosis Homes in New York City."

"X-Ray Jamborees."—October 15 marked the beginning of Harlem's chest x-ray jamborees, the highlight of a two month antituberculosis campaign in the community. Free chest x-rays are being offered during the campaign to every adult resident of Harlem, an area where tuberculosis still kills nearly ten people every week, according to the state health department. The sponsoring groups are the Central Harlem Health Center of the state department of health, the Harlem Tuberculosis and Health Committee of the New York Tuberculosis and Health Association and the Manhattan Central Medical Society.

Dr. Muckenfuss Returns.—Dr. Ralph S. Muckenfuss, New York, who commanded the first medical general laboratory in the European theater of operations and the European theater blood bank, has returned from military service to resume his position as director of the bureau of laboratories of the department of health. Dr. Muckenfuss had been on military leave since July 22, 1942. In a citation awarding him the Legion of Merit, Dr. Muckenfuss, who held the rank of lieutenant colonel, was credited with organizing the first medical general laboratory, the first organization of its type. The credit for organizing the only blood bank in the United Kingdom was also ascribed to him.

Blood and Plasma Exchange Bank.—The Medical Society of the County of New York has incorporated a nonprofit organization to make blood and plasma readily available to patients in civilian hospitals at a small cost, the *New York Times* announced October 4. The new organization will be known as the Blood and Plasma Exchange of New York Incorporated and replaces a project organized by the society four years ago which was a cooperative affair among 150 hospitals in the metropolitan area. The new corporation will have a five fold program:

To coordinate existing facilities and institutions in the New York metropolitan area for the obtaining, processing, typing, matching, transportation and supply of human blood, blood plasma and related products.

To reduce the cost and to improve and increase the supply of human blood, plasma and related products for patients in the hospitals in the New York metropolitan area.

To conduct and support research projects in the operation of human blood banks and the improvement of their procedures.

To finance the training of technical personnel for the operation of human blood banks.

To stimulate and, if desirable, to subsidize the development and operation of additional blood banks in hospitals in various regions of the metropolitan area.

Heretofore the cost of a pint of blood for transfusion has been \$41, but in the new arrangement a patient may obtain a unit of processed blood or plasma without any charge if he arranges through his family or friends to reimburse the hospital bank with two units of unprocessed blood. If no blood is replaced, the charge is \$15 for the unit. The New York Times states that grants will be sought from various foundations to permit a program of expansion and improvement. One of the purposes to which these funds will be devoted will be the establishment of a twenty-four hour a day telephone and delivery service operated through a central office where an inventory of the supplies of blood of all types, plasma and blood derivatives will be kept. The technical policies of the Blood and Plasma Exchange Bank have been determined by a board of governors consisting of the superintendents and transfusionists of the eight supplying hospitals, together with representatives of three of the receiving hospitals and the deputy commissioner of health. The board of directors of the new corporation will include eventually representatives of the county medical society, the city's health and hospital departments, the Greater New York Hospital Association and other agencies.

OHIO

Physician's Estate Goes to Library.—On the death of his widow, the entire estate of the late Dr. Frederick W. Walz, Cleveland, will go to the trustees of the Cleveland Public Library "to promote the welfare of the community."

Society Holds 101st Meeting.—The Northwestern Ohio Medical Association, said to be oldest organization of its kind in the state, held its one hundred and first meeting October 9 at the Commodore Perry Hotel, Toledo. Speakers included Dr. Edward J. McCormick, Toledo, Chairman of the Council on Medical Service and Public Relations, American Medical Association, on "What Lies Ahead for the Medical Profession," and Charles Coghlan, executive vice president of Ohio Medical Indemnity.

OREGON

State Society Collects Material on Its Service Members.—The Oregon State Medical Society is assembling documents and photographs, in addition to other pertinent material, of physicians who have participated in World War II, whether members of the society or not, to build up a record of Oregon's contribution in medical activities of the war. Before the collection is permanently deposited in the medical library, to be made available to historians, it will be turned over to a World War II History Project, which will have it arranged, analyzed and catalogued by trained personnel, with duplicate catalogue cards filed in the Oregon Historical Society, the state archives, the medical school library and probably the University of Oregon Library, the Oregon State College Library and the Portland Public Library. The Oregon World War II History Project is under the direction of competent historians, Luther S. Cressman, Ph.D., curator of anthropological and director, Museum of Natural History, University of Oregon; Mr. Lancaster Pollard, superintendent, Oregon Historical Society; Dan Clark, department of history, University of Oregon; and Miss Gladys M. Everett, War Public Services, Federal Works Agency. It is part of the national program originally initiated by the committee for the conservation of the cultural resources, a national organization operating on the state level.

PENNSYLVANIA

Philadelphia

Dr. Sokoloff Named Chief of Tuberculosis Division.—Dr. Martin J. Sokoloff, acting chief of the division of tuberculosis of the department of Health, has been appointed chief of the division, according to *Philadelphia Medicine*.

The Pancoast Lecture.—Dr. Ross Golden, professor of radiology, Columbia University College of Physicians and Surgeons, New York, will deliver the fifth Henry K. Pancoast memorial lecture before the Philadelphia Roentgen Ray Society November 1. His subject will be "Some Problems in Abnormal Intestinal Physiology Associated with Peritoneal Adhesions and Ileus."

Changes at Woman's Medical College.—Among recent appointments of the faculty of the Woman's Medical College of Pennsylvania is that of Dr. Virgene M. Scherer-Wannock as clinical assistant professor of syphilology. Promotions of the faculty include:

Dr. Margaret De Rinde to clinical associate professor in psychiatry.
Dr. Mary R. Earch to clinical assistant professor of medicine.
Dr. Mildred C. J. Pfeiffer to clinical assistant professor of medicine.
Maria Wiener, Ph.D., to assistant professor of bacteriology.
Dr. E. Marian Williams to clinical assistant professor of gynecology.

Association of Ex-Resident and Resident Physicians.—The fifty-ninth annual dinner of the Association of Ex-Resident and Resident Physicians of the Philadelphia General Hospital will be held on Tuesday, December 4 at the Bellevue-Stratford Hotel, Broad and Walnut streets, at 7 o'clock. The president of the association, Dr. Lyn W. Deichler, Philadelphia, will preside and act as toastmaster. Ex-residents who do not receive notices of the annual dinner are requested to send their correct addresses to the secretary, Dr. Robert C. McElroy, 133 South 30th Street, Philadelphia 4.

GENERAL

Medical Correctional Association.—The annual meeting of the Medical Correctional Association, an affiliate of the American Prison Association, will be held at the Hotel Pennsylvania, New York, November 15-16. The meeting will be a joint session with the committee on crime prevention of the American Prison Association and includes the following speakers:

Dr. Robert V. Seliger, Baltimore, Criminal Hygiene.
Dr. Frank J. Conroy, New York, Group Treatment of Criminals.
Robert M. Lohrer, Ph.D., Baltimore, Practical Mental Hygiene for the Prisoner.
Dr. Ralph S. Banay, New York, Wanted—An Institute of Criminal Science.
Nesley K. Teeters, Philadelphia, Fundamentals of Crime Prevention.
Sophie Roldson, New York, Wanted—An Index for Crime and Delinquency.

Illegal Prescriber of Narcotics.—The Bureau of Narcotics, U. S. Treasury, reports that one Kenneth M. Crinkshank has been charged with violation of the federal narcotic law, having exceeded twelve fictitious narcotic prescriptions in law, while posing "as a physician from the Mississippi State Board of Health." The U. S. Attorney at Jackson has lodged a detainer against the defendant, who is now in the U. S. Public Health Service Hospital, Lexington, Ky., to which institution he was returned for violation of his probation in a case which originated at Detroit in January 1944. The Bureau of Narcotics states that Crinkshank's criminal record dates back to 1928, at which time he was 25 years old and addicted to narcotic drugs. His criminal record shows various sentences to the house of correction and Leavenworth penitentiary as well as commitment to the U. S. Public Health Service Hospital at Lexington for treatment for narcotic addiction.

Borden Award in Nutrition.—The American Institute of Nutrition will make this award in recognition of distinctive research by investigators in the United States and Canada which has emphasized the nutritive significance of the cow-milk which has emphasized the nutritive significance of the cow-milk which has emphasized the nutritive significance of the cow-milk. The award will be made primarily for the publication of specific papers, but the judges may recommend that it be given for important contributions over an extended period of time. The award may be divided between two or more investigators. Employees of the Borden Company are not eligible for this honor. The formal presentation will be made at the annual meeting of the institute in the spring of 1946. To be considered for the award, nominations must be in the hands of the chairman of the nominating committee by January 15. The nomination should be accompanied by such data relative to the nominee and his research as will facilitate consideration for the award. W. E. Kraus, Ohio Agricultural Experiment Station, Wooster, Ohio, is chairman of the nominating committee.

Council Named for Eye Bank.—Seventy-five persons have been appointed to serve as members of a council sponsoring the work for the Eye Bank for Sight Restoration, Inc. The council, with Albert G. Milbank as chairman, will aid in the plan to establish a nationwide eye bank for obtaining and making available healthy corneal tissue to restore the vision of persons whose sight has been lost through disorders of the cornea. The plan which the council is sponsoring includes research, study and instruction of ophthalmologists in the delicate surgery required in performing the corneal graft operation. Fellowships which will enable advanced study in causes of corneal disorders and in methods to increase the time which corneal tissue may be preserved and made available for use.

in sight restoration operations are also included in the plan. Similar to the function of blood banks in restoring exhausted blood supply, the eye bank was organized to make possible restoration of the sight of persons whose vision has been destroyed because of corneal disorders by replacement with healthy tissue from the eyes of other persons (*THE JOURNAL*, April 21, p. 1067).

Clinical Fellowships in Medicine.—In order to assist in providing opportunities for postgraduate education in internal medicine for medical officers discharged from the armed forces, the American College of Physicians has established a limited number of clinical fellowships in medicine for 1946. These fellowships are available for physicians honorably discharged from the armed forces who are fellows, associates or prospective candidates for associateship in the college. They are designed to provide opportunity for advanced clinical training in internal medicine or in any of its special fields. They are limited to a term of one year, may start at any time during 1946 and will not be renewable. Assurance must be provided that the applicant will be acceptable in the clinic in which he has chosen to work. The fellowship stipend will ordinarily be from \$1,800 to \$3,000 depending on individual circumstances. Application forms for these fellowships will be supplied on request to the American College of Physicians, 4200 Pine Street, Philadelphia 4, and may be submitted, in duplicate, at any time. Decision with respect to award of a fellowship will be made and the applicant notified of the action taken as soon as possible after receipt of the application. Dr. Francis G. Blake, New Haven, Conn., is chairman of the committee on fellowships and awards.

Comparison of War and Accident Casualties in Second World War.—The National Safety Council has prepared the following tabulation showing a comparison of wartime casualties between Dec. 7, 1941 and VJ day, August 14:

WAR CASUALTIES (From the Army and Navy)

Killed	261,608
Wounded	651,911
Missing	32,811
Prisoners	124,194
Total	1,070,524

THE HOME FRONT ACCIDENT TOLL (From the National Safety Council)

Killed	355,000
Injured	36,000,000
(Including 1,250,000 cases involving some permanent disability)	

ACCIDENT TOLL TO WORKERS ALONE (On and Off the Job)

Killed on the job..... 66,000	Total workers killed on
Killed off the job..... 94,000	and off the job..... 160,000
Injured on and off the job.....	15,000,000
(Including 860,000 cases involving some permanent disability)	

THE TRAFFIC TOLL ALONE

Killed	94,000
Injured	3,300,000
(Including 270,000 cases involving some permanent disability)	

THE TOLL IN HOMES ALONE

Killed	118,000
Injured	17,500,000

Howard Rusk Named Consultant on Physical Rehabilitation.—Col. Howard A. Rusk, M. C., has resigned from the army to serve as consultant on physical rehabilitation for the Baruch committee on physical medicine, New York. The announcement indicated that Dr. Rusk is serving the committee temporarily in an effort to apply his army experience in physical rehabilitation to the urgent civilian needs in this phase of physical medicine. The committee plans to set up a blue print for the guidance of communities in the establishment of community rehabilitation centers for service. Although the committee is not in the position to finance the construction and operation of these centers, it will, through Dr. Rusk and other authorities on rehabilitation, make up a formula for a general organization to handle the program in the various communities of the nation. The formula will contain estimates of the personnel and physical facilities required for an effective center together with the necessary administrative and professional procedures. It is estimated that there are twenty-three million persons in the United States who, through injury, disease, maladjustment or from their experiences in former wars, are in need of physical or functional rehabilitation or both. It is estimated that at present there is a backlog of one million people who are in need of such care to make them employ-

able. There were forty-four thousand people in 1944 who had undergone such care. Their average income before such rehabilitation was started was \$162 annually per person. The first year after such rehabilitation their average income was \$1,750 per person. This rehabilitation work is considered the third phase of medical care, the first phase being preventive medicine and the second diagnosis and treatment. Colonel Rusk, before the war, practiced internal medicine in St. Louis and also was instructor in medicine at Washington University School of Medicine there. In December 1942 he established for the Army Air Forces at Jefferson Barracks the first rehabilitation program in the armed forces. In 1943 he was given the Lord and Taylor American Design Award for a notable contribution in the field of rehabilitation. For the past several months he has been chairman of the subcommittee on civilian rehabilitation centers of the Baruch committee.

CANADA

Medical Committee on Atomic Energy.—Chalmers J. Mackenzie, D.Sc., president of the Canadian National Research Council, Ottawa, has announced that a special medical committee has been appointed to act as general directing body on medical research in the field of atomic energy, according to *Science*. The members are Drs. Duncan Graham, Toronto; James B. Collip, Montreal, and Dr. Joseph S. Mitchell, Montreal.

LATIN AMERICA

Health Activities in Latin America.—*Latin American Medical Association Formed.*—A new inter-American organization, open to physicians from all over the hemisphere, has been formed under the name of the Latin American Medical Association. At its first meeting in Mexico City, held recently, the following officers were chosen: Drs. Juan Rafael Herradora-Ubeda, Jersey City, N. J., president; Pedro Jose Zepeda, vice president; Gonzalo Valdes, secretary; Manuel de la Torre Morali, assistant secretary, and Victorio Lorani, director. Headquarters are in Mexico City. Its object is to promote the scientific advantage of medicine through the interchange of all problems except those of a religious or political nature. It hopes to organize lectures and postgraduate courses, award prizes and honorary mention for meritorious contributions to medicine in the hemisphere and establish closer relations with North and South American medical groups. It has also taken over sponsorship of the Spanish language medical journal *El Progreso Medico* (Medical Progress), which has already been published for six years.

Colombia Plans Socialized Medicine.—According to Dr. Carlos Vera, Cucuta, a physician attached to the social welfare department of the province of Santander, Colombia, the country is planning a program of socialized medicine which will affect workers in both industry and government. The physician arrived in Miami, Fla., September 24, on a commission by the Colombian government to study social security laws in the United States, according to the *Pan American World Airways*.

Argentine-British Medical Center in Buenos Aires.—An Argentine-British Medical Center has been established in Buenos Aires, with the assistance of the British Council, to promote closer relations and to facilitate the exchange of information between the British and Argentine medical professions, according to the *British Medical Journal*. The center has a committee of honor, the twenty-two Argentinian members of which include Drs. Jose Arce, Pedro Escudro, Bernardo A. Houssay and Alfredo Sordelli. British representatives of various branches of medicine have been invited to join this committee. On the executive committee are the president of the center, Dr. Mariano R. Castex; the director, Dr. Antonio Egués; the secretary, Dr. R. Castro O'Connor; an assistant secretary, three ordinary members, and two representatives of the British Hospital in Buenos Aires.

Special Society Elections.—Recently elected officers of the Sociedade de Pediatria da Bahia, Brazil, are Drs. Eliezer Audifac, president; Arnaldo Santana, vice president, and Elisio Athaide and João Pedroza Cunha, secretaries. —Recently elected officers of the Sociedad de Pediatria de Córdoba are Dr. Juan Francisco Herrera, president; Dr. J. Nicola Beltramo, vice president; Dr. Bernardo Serebrinsky, secretary, and Horacio H. Sanchez, treasurer.

New Director of Finlay Institute.—Dr. Arturo Curbelo Hernandez, professor of bacteriology of the University of Havana School of Medicine and Pharmacy, has been appointed director of the Finlay Institute of the Americas.

The Socialist Government and the British Medical Association

The socialist government has been sobered by experiencing the responsibilities of office. The speeches of its members are full of the difficulties which confront them on the path to the promised utopia of their election addresses and differ little from the addresses made by members of the late government. This is illustrated in a speech made by Mr. Bevan, the new minister of health, as the guest of the Royal Medico-Chirurgical Association at its annual dinner. Mr. Bevan said that the framing of a national health service was a task of great perplexity and delicacy in which he invited the cooperation of the medical profession. He knew that he had to break down some suspicions, but he was distinctly optimistic and believed that before the end of another year we would have a medical service which would make Britain the envy of other nations. A nation which had achieved so much during the last six years would not fail to surmount the difficulties. The war had destroyed many hospitals, and there was a shortage of nursing staff. It was the function of the Ministry of Health to provide physicians with the best and the most modern apparatus of medicine and to enable them to use it freely in accordance with their training. The individual citizen must be free to choose his doctor; the doctor must be able to treat his patient in conditions of privacy. He regarded the general practitioner as the most important man in the medical profession. He knew that there were doctors who felt that a state medical service was likely to be too much under the control of a bureaucracy. But, though he was a socialist, he believed in industrial democracy and therefore felt that doctors as a profession must have a greater and greater voice in the management of their own services, exactly as he wanted similar power for miners, railway men and engineers. But he was going to do many unorthodox things, to try a number of experiments, in which he hoped to have the cooperation of the medical profession. It will be obvious that this declaration of policy is very different from that reported in a previous letter, in which Bevan denounced his predecessor, the conservative minister of health, for surrendering to the medical profession, although he entered into negotiation, the very thing now foreshadowed.

Dr. Charles Hill, secretary of the British Medical Association, said in reply that Mr. Bevan's human and reassuring speech encouraged confident expectations. When Mr. Bevan met the doctors he would find men no less earnest than himself for the health of the people. It had become fashionable to regard individual doctors with love and respect and doctors collectively as reactionary and opposed to the public interest. They would soon, he hoped, be able to convince yet another minister that the profession had the fullest intention and desire to cooperate in obtaining the best possible health service. But Dr. Hill did not believe that the best public interest would be served by converting an independent profession into a branch of central or local government.

Organizing the Use of Medical Films

A scientific film association was formed in 1943 for the collection, collation and distribution of scientific films and to promote their appreciation and use. In July 1944 a medical standing committee was formed under the chairmanship of Mr. McAdam Eccles, a surgeon. In cooperation with the association a catalogue of all the medical films in Britain is now being prepared, which is regarded as an important work. It

will list all the medical films known to exist here and will record under each title a summary of content and critical appraisal, prepared by a panel of experts in the subject matter depicted, as well as the usual details of availability and length. As new films are completed details will be given in supplements, and films withdrawn from circulation will be noted. A comprehensive recording system is used which other countries are considering. The catalogue will probably be published part by part, and first instalments are expected toward the end of this year. The medical committee of the association has already presented eighteen films at the Royal Society of Medicine to audiences averaging over 200. A new selection devoted to specialized subjects is being planned for the autumn. A memorandum on films required to be made immediately for use in teaching is being drawn up. A letter sent out earlier in the year to the deans of medical teaching schools has brought many detailed replies, on which the memorandum will be based. The correspondence of the committee now extends overseas to organizations in Australia, Canada and the United States and to individual members in other countries.

DDT as Malaria Preventive

A new use for dichlorodiphenyl trichloroethene, which has proved so useful in the destruction of noxious insects, is predicted. Indian army medical authorities, with the cooperation of the Indian air force, are testing the possibilities of reducing malaria in India by spraying DDT from the air. The first trial was made at Delhi on the banks of the Jumna, a breeding area for mosquitoes too large to be controlled effectively by ground methods. Entomologic data collected by the Malaria Institute of India before and after spraying showed that adult mosquitoes had been reduced by as much as 50 per cent on some parts of the ground sprayed while the larvae had been destroyed over the entire area. Experiments are to be continued in other malarial areas of the country.

PARIS*(From Our Regular Correspondent)*

Sept. 29, 1945.

Syphilis and Social Measures of Prevention

At a meeting of a permanent committee on social hygiene at the Ministry of Public Health Dr. Cavaillon gave the results of a study made by him and Dr. Renard on the course of syphilis from 1921 to 1944. In twenty cities the cases of primary syphilis are as follows: 1921, 2,400 cases; 1927, 900; 1931, 1,500; 1938, 600; 1941, 600; 1942, 900; 1943, 1,200; 1944, 1,400. This recrudescence of syphilis is to be explained by war and occupation. The difficult economic situation has contributed to increased clandestine prostitution, which is one of the main causes of venereal diseases. The minister of the interior, acting on a proposal of the minister of public health, has taken several measures to combat clandestine prostitution. Steps are to be taken to find out prostitutes through inquiries and controls, with frequent inspections in bars, music halls, dance halls, cabarets and other places of amusement. The sick will be sent to a hospital or clinic. Those with a profession from which they derive a normal income will not be subjected to the degrading measure of the "prostitutes' police card." They will have to submit to compulsory sanitary control at least once a week; this will include on each occasion a serologic and bacteriologic examination. The prostitutes will then receive a medical certificate, which they must always carry with them. The prostitute who will not submit to these examinations or who is too often absent from the examinations without proving a change of life can be submitted to the "police card."

The minister of public health has sent a circular to doctors, hospitals and venereal disease centers emphasizing the necessity

of intensifying the search for cases of recent and old syphilis and of the occult type. He prescribed, among other measures, the medical inspection of employees of big industrial and commercial concerns and of administration offices as well as the permanent attendance and medical control of families of patients affected with dementia paralytica. He insists on the obligation of tracing venereal diseases by compulsory medical prenuptial examination, by the two antepartum examinations and by the medical control of milk handlers, wetnurses, nurses and all persons attending children.

Trend of the Demography of Paris

Marcel Mome, statistician to the Comité National de la Defense Contre la Tuberculose has reported vital statistics for Paris and the department of the Seine.

According to the table the lowest birth rate occurred in 1939-1940 on account of the mobilization, the 1943 rate was higher but did not reach that of 1935. At the same time the mortality rate, which diminished in 1939, reached 37,207 deaths in 1944, and this with reference to a diminished birth rate, as against 34,698 in 1935. The birth rate is lower in the districts inhabited by people in good circumstances—down to 58 per 10,000 inhabitants, as against 114 per 10,000 for the

Births and Deaths During Ten Years

Years	Paris		Seine	
	Live Births	Deaths, Not Including Stillborn	Live Births	Deaths, Not Including Stillborn
1900	33,047	34,098	63,734	64,006
1906	32,196	34,620	62,014	63,308
1907	31,041	33,709	61,069	63,008
1908	30,976	33,572	60,830	63,984
1909	24,804	30,150	49,043	58,035
1910	22,670	31,637	44,310	61,767
1911	20,301	30,600	48,474	60,637
1912	28,690	30,150	51,410	66,001
1913	31,030	33,097	54,767	59,610
1914	29,668	37,207	51,999	65,160
Totals	290,208	340,508	548,660	637,961
Deficit		50,230		80,301

entire population. As to mortality, the districts having the highest birth rate are most affected. Moreover, Mr Mome gives a death rate of 152 per 10,000 inhabitants for the poorer districts, as against 76 for those having a fair standard of living.

The author contends that with some adjustments these statistics can be applied on a national scale.

In order to remedy this low birth rate, says the author, it is not enough to recommend more large families. To guarantee a sufficient natality and healthy children the level of general hygiene must be improved, healthy lodgings must be procured, social disease (such as tuberculosis) must be energetically combated. Moreover, the disappearance of underfeeding and its consequences will effectively contribute to improvement in the situation.

Death of Marc Tiffeneau

Marc Tiffeneau, whose death occurred at the age of 73, had been professor of pharmacology and medicine at the Faculté de médecine since 1926. He had been a member of the Académie de médecine since 1927 and of the Académie des sciences since 1939. In the late Society of Nations he was also a member of the Committee on International Control of Narcotic Drugs. His researches regarding general hypnotics and anesthetics and tuberculin are well known. Ouabain was discovered in his laboratory. Under the occupation he belonged to the Medical and University Resistance Movement.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, Sept 22, 1945

Military Medicine News

The War Department has released for publication some information about the medical assistance to the wounded Brazilian soldiers returning from Italy and treated at the Army Central Hospital of Rio de Janeiro under the direction of Col Florencio de Abreu. The first group of evacuated soldiers arrived at Rio de Janeiro in September of last year, a little more than two months after the first contingent of troops departed from this city. Little by little more wounded soldiers arrived. Up to the date of the release, the Army Hospital has received 1,068 wounded soldiers, of which about 75 per cent are entirely cured or in course of convalescence. The remaining 25 per cent have been discharged, as they have been considered incapacitated for service. Of all the 1,068 evacuated soldiers, only 1 died at the hospital. The Brazilian Army Medical Corps has adopted all the American methods of handling the wounded soldiers.

After their discharge from service and return to civil life, some of these wounded persons will still need the care of reconditioning and rehabilitation, a task that has to be done in part by the orthopedic services of the municipal hospitals of the city of Rio de Janeiro. For this reason the surgeons of these hospitals are being prepared for this special work. The first step in preparation has been the presentation, by the Bureau of Health Information, in cooperation with the Division of Moving Pictures of the Coordinator of Inter-American Affairs, of some useful medical films prepared by the United States Army and lent by Col Howard R. Lackay, M. C., U. S. Army, of the Brazil-United States Military Commission. The subject of the films has been explained by Lieut Emidio S. Montenegro of the medical corps of the Brazilian army.

Drs Alfredo Monteiro, Ernani Alves, Estelita Lins, Mazzini Bueno and several other prominent surgeons who served in the Brazilian Expeditionary Force in Italy have recently arrived from Europe. The National Academy of Medicine, the Rio de Janeiro Society of Medicine and Surgery and the Brazilian College of Surgeons have held special meetings to greet these surgeons. A few of them have read papers describing the advances of surgery in the present war, particularly at the front in Italy.

Personal

Dr J. Barcala, associate professor of neurology at the University of Buenos Aires, spent a few days in Rio de Janeiro. At the medical department of the Bureau of Fisheries of the Ministry of Agriculture, he read a paper on the diagnosis and surgical treatment of sciatica.

Dr I. L. Nyes Manta, associate professor of clinical psychiatry at the University of Rio de Janeiro, has been elected a member of the National Academy of Medicine of this city.

Marriages

WILLIAM LADELLE HOWELL, Fort Worth, Texas, to Miss Patricia Herbst in Washington, D. C., August 20.

JAMES FRANCIS KEGAN, Burke, Idaho, to Miss Rose Antoinette Ewald of Wytheville, Va., September 1.

GEORGE P. JONES JR., Memphis, Tenn., to Lieut Sarah Martha Goodson at Atlanta, Ga., August 28.

ALFRED JARFTZKI III, New York, to Miss Sonia Lasell in Whitinsville, Mass., August 31.

MAX M. GITLIN, Bluffton, Ind., to Miss Mary Lawson at Seattle, August 16.

THEODORE S. HOWELL, Houston, Texas, to Miss Mildred Hendrix recently.

Deaths

Henry Alexander Miller, Philadelphia; Yale University School of Medicine, New Haven, Conn., 1933; D.D.S., Evans Institute, University of Pennsylvania, in 1929; born in New Haven, Conn., Oct. 10, 1904; specialist certified by the American Board of Plastic Surgery and the American Board of Otolaryngology; diplomate of the National Board of Medical Examiners; member of the American Medical Association, College of Physicians of Philadelphia and the Philadelphia Laryngological Society; first lieutenant, medical reserve corps, U. S. Army, not on active duty; instructor in maxillofacial surgery at the University of Pennsylvania Graduate School of Medicine; chief, department of radiology, visiting oral surgeon, Philadelphia General Hospital; affiliated with the Post-Graduate, Presbyterian, Children's, University of Pennsylvania and Chestnut Hill hospitals; associate editor of the *Dental Digest*; died in the University of Pennsylvania Hospital July 14, aged 41, of acute endocarditis.

Henry Hedden, Memphis, Tenn.; M.B. in 1916 and M.D. in 1918, Queen's University Faculty of Medicine, Kingston, Ont., Canada; served in the medical corps of the Canadian army during World War I; a founder and first president of the *Memphis Hospital Association* and the *Tennessee Hospital Association*; served as president of the *Southeastern Hospital Association* and of the *Hospital Association of the Methodist Episcopal Church, South*; a charter fellow of the *American College of Hospital Administrators* and formerly a regent of region number six; member of the *American Hospital Association* and the *American Protestant Hospital Association*; at one time superintendent of the General Hospital in St. John, N. B., Canada; superintendent and trustee of Porter Home and Leath Orphanage; superintendent of the Methodist Hospital, where he died July 30, aged 54, of cerebral hemorrhage.

Walter Nixon Thompson * Sullivan, Ind.; Rush Medical College, Chicago, 1886; one of the founders and at various times president of the Sullivan County Medical Society; has been affiliated with the *Associated Anesthetists of the United States and Canada*; served as a captain in the medical corps of the U. S. Army during World War I; captain, medical reserve corps, U. S. Army, not on active duty; one of the founders of the R. H. Crowder Memorial Hospital; first president of the Mary Sherman Hospital; in February 1936 was given a banquet by the Sullivan County Medical Society in recognition of his fifty years in the practice of medicine in Sullivan; died July 17, aged 80, of carcinoma of the stomach.

Albert Harold Aland * Los Angeles; Western Reserve University School of Medicine, Cleveland, 1916; member of the Utah State Medical Association and the Pacific Coast Otolaryngological Society; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; served as demonstrator of anatomy at his alma mater; at one time on the staffs of the Charles T. Miller Hospital in St. Paul and St. Mary's Hospital in Minneapolis; formerly head of the eye, ear, nose and throat department, Thomas D. Dee Memorial Hospital in Ogden, Utah; on the staffs of the Santa Monica (Calif.) Hospital and St. John's Hospital; died July 24, aged 56, of coronary occlusion.

James Sutcliffe Hill * Bellows Falls, Vt.; University of the City of New York Medical Department, 1884; health officer; honorary member of the Vermont State Medical Society; for many years secretary of the board of pension examiners for Windham County, surgeon for the Rutland Railroad and member of the New York and New England Association of Railway Surgeons, of which he had been president; on the staff of the Rockingham General Hospital; served as a member of the Rockingham Library Board for many years, part of the time as secretary of the board and in late years as president; died July 2, aged 85, of carcinoma of the stomach.

John Dickenson, Shaker Heights, Ohio; Western Reserve University Medical Department, Cleveland, 1901; member of the American Medical Association; past president of the Academy of Medicine of Cleveland; fellow of the American College of Surgeons and past governor of the board; served as chairman of the central committee of Ohio on fractures and dislocations of the American College of Surgeons; a trustee of the Cleveland Medical Library Association; assistant clinical professor of surgery at his alma mater; formerly chief of staff at St. Vincent Charity Hospital, Cleveland, where he died July 9, aged 68, of arteriosclerosis.

James A. Alexander, Indianola, Miss.; Medical College of Alabama, Mobile, 1888; veteran of the Spanish-American War; died in the Veterans Administration Facility, Memphis, July 21, aged 79, of carcinoma.

Marian Arvine-Coleman, New York; Eclectic Medical College of the City of New York, 1900; died July 22, aged 75, of cerebral hemorrhage.

Henry E. Bartling, Pacific, Mo.; Beaumont Hospital Medical College, St. Louis, 1894; member of the American Medical Association; died June 16, aged 73, of diabetes mellitus and subacute nephritis.

Alex McNeill Blue, Carthage, N. C.; Tulane University of Louisiana School of Medicine, New Orleans, 1915; member of the American Medical Association; on the courtesy staff of the Moore County Hospital; formerly part time county health officer; died July 11, aged 58, of pulmonary thrombosis.

William Alva Brady, Union City, N. J.; University of Vermont College of Medicine, Burlington, 1901; member of the American Medical Association; examining physician for the Hudson County Selective Service appeal board; served during World War I; veterans' medical examiner during World Wars I and II; formerly mayor of Union City; physician for the Hudson County Penitentiary; died in Keene, N. H., July 14, aged 69, of intestinal obstruction.

George L. Carder, Hagerstown, Md.; University of Maryland School of Medicine, Baltimore, 1891; died in the Washington County Hospital July 19, aged 81, of chronic myocarditis and bronchopneumonia.

Stephen Adelbert Craig * Ontario, Calif.; College of Physicians and Surgeons, medical department of the University of Southern California, Los Angeles, 1919; served during World War I; died June 26, aged 52.

William Jordan Davis, St. Louis; St. Louis University School of Medicine, 1906; died in the Pike County Hospital, Louisiana, Mo., July 28, aged 70, of carcinoma of the stomach.

Lee O. Greene, Pea Ridge, Ark.; St. Louis College of Physicians and Surgeons, 1902; member of the American Medical Association; died in Bentonville July 4, aged 65, of cerebral hemorrhage.

Frank Tucker Hopkins, New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1885; member of the American Medical Association and the American Otolaryngological Society, Inc., for many years connected with the New York Eye and Ear Infirmary and St. Luke's Hospital; died July 5, aged 88, of pneumonia.

William James Howard, Washington, D. C.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; died in the Freedmen's Hospital July 6, aged 63, of shock following a prostatectomy.

John Robert Kennedy, DeQueen, Ark. (licensed in Arkansas in 1903); died June 10, aged 75, of cerebral hemorrhage.

Paul Duncan McGehee * Mobile, Ala.; University of Alabama School of Medicine, 1910; died July 10, aged 59, of cardiorenal vascular disease.

James H. Moroney, Winchester, Ind.; Starling Medical College, Columbus, 1885; member of the American Medical Association; served as city and county health officer; on the staff of the Randolph County Hospital; died July 8, aged 89, of chronic myocardial failure.

John E. Oakley, Memphis, Tenn.; Memphis Hospital Medical College, 1900; died in the Baptist Memorial Hospital July 3, aged 65, of coronary thrombosis.

Edwin Spooner Potter, Santa Barbara, Calif.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; served during World War I; major, medical reserve corps, U. S. Army, not on active duty; died July 6, aged 75, of cerebral hemorrhage.

John William Ridenour, Ada, Ohio; Eclectic Medical Institute, Cincinnati, 1899; died July 10, aged 77, of carcinoma of the intestine.

Clement Dare Smedley, Youngstown, Ohio; Medical College of Ohio, Cincinnati, 1903; served during World War I; died July 8, aged 69, of carcinoma of the rectosigmoid.

Anna Topaz, Providence, R. I.; Tufts College Medical School, Boston, 1903; for many years on the staff of the Miriam Hospital; died June 19, aged 73, of injuries received when struck by a trolley car.

Edward Comstock Wilson, * * * * * 1907; Washington University School of * * * * * edema, coronary heart disease and arteriosclerosis.

Correspondence

EARLY HEALING IN FRACTURES

To the Editor:—Referring to a communication of mine published in *THE JOURNAL*, August 4, under the heading "Early Healing in Chronic Osteomyelitis and Compound Fractures," I have just received a letter from Col. Leonard T. Peterson, M. C., U. S. Army, on duty in the Surgeon General's Office.

Dr. Peterson calls my attention to the fact that early work along the lines I discuss was done in the Mediterranean theater by Col. E. D. Churchill, who was making some use of secondary closure in compound fracture wounds. The second point to which Colonel Peterson calls attention is that Capt. E. M. Burgess was preceded in the use of skin graft for earlier closing of such wounds by Major Robert P. Kelly, chief of the orthopedic section at Ashford General Hospital, White Springs, W. Va. Colonel Peterson says that Major Kelly discussed this method at our meeting of the American Orthopedic Association in 1944.

With regard to either primary or secondary closure of these wounds, that has been described and discussed by many surgeons ever since Chisholm of the Confederate Army advocated it during the Civil War. I am still opposed to that for the reasons that I have stated on many occasions. With regard to the skin graft covering of wound surfaces, however, that is a distinct contribution to the program I have been advocating, and I am glad to refer credit back to Major Kelly, as suggested.

H. WINNETT ORR, M.D., Lincoln, Neb.

ACUTE SECONAL POISONING

To the Editor:—I have just read with much interest the report by Wheelock and Freedman (*THE JOURNAL*, September 8, p. 130) under the caption "Acute Seconal Poisoning." My attention was especially arrested by the sentence which reads "A survey of the literature has failed to reveal any cases of seconal poisoning which terminated fatally."

Obviously the writers of that article, even though they may have heard of the late lamented Will Rogers, did not follow his example and "read the daily papers." Had they done so I am certain that they would have seen the news articles on the death of the noted evangelist Amy Semple McPherson, which occurred at the Leamington Hotel in Oakland, Calif., about a year ago. And I am equally sanguine that they would have noted therein the fact, established by the medicolegal autopsy performed by Dr. Gertrude Moore, that the cause of death was an overdose of sodium isoamylal, commercially known as "seconal."

I am induced to proffer this commentary since I believe it will serve to place needed emphasis on the all too frequent appearance of references to "the literature" without notation as to the thoroughness with which such search has been pursued. Likewise it serves to stress the fact that the 'scientific literature,' despite its great volume, is not all inclusive by any means, and that especially in the realm of legal medicine and toxicology a search has not been complete until it has embraced a study of the court abstracts published for each of several sections of this country, and in several foreign countries as well, and also has included a scanning of the daily, weekly and monthly secular publications, which habitually print news items or commentaries on such occurrences.

If the authors, or any other interested and qualified persons, desire the data regarding the findings in the case of Amy Semple McPherson, I am sure that such could be obtained from either the district attorney of Alameda County or from Dr. Moore.

ALBERT G. HULETT, M.D., Oakland, Calif.

Director of Laboratories, Alameda County.

A WARNING CONCERNING THE PROMISCUOUS USE OF CURARE IN POLIOMYELITIS

To the Editor:—Considerable interest has been aroused by Dr. Nicholas S. Ransohoff's preliminary report on the use of curare in 4 cases of acute poliomyelitis (*THE JOURNAL*, September 8, p. 129). Interest is perhaps greater in areas where the disease has reached epidemic proportions, as is true in Salt Lake City.

Despite the fact that much remains to be learned about the pharmacologic aspects of curare, particularly its effects on the central synaptic transmission, all investigators are agreed that it is a most powerful agent in causing peripheral neuromuscular paralysis and is capable of producing respiratory paralysis and death.

Kabat and Knapp (*J. Pediat.* 24:123 [Feb.] 1944) have described the effects of anesthetic agents and beta-erythroidine on muscle hypertonicity in poliomyelitis. My own experience with the use of curare for the same purpose was reported in another connection (*Rocky Mountain M. J.* 41:313 [May] 1944) and relief of hypertonicity was found to be transitory, as a rule, even when patients receive sufficient curare to produce complete respiratory arrest.

Curare is perhaps one of the greatest aids added to the anesthesiologist's armamentarium in recent years. While practically all observers are in agreement with regard to the low toxicity of curare when properly employed, it is a dangerous weapon in the hands of the inexperienced and untrained. Its use should be reserved for those who are familiar with its clinical and pharmacologic actions, its untoward effects and the precautions necessary to avoid them. Particularly, one should be capable of performing endotracheal intubation for administration of artificial respiration.

Curare should be administered with caution, especially to patients having respiratory embarrassment or impairment in function of the throat muscles. By its own action the drug can make it difficult or even impossible for a patient to swallow, cough or expectorate and can cause death from respiratory paralysis.

Curare should be administered only when the following conditions have been fulfilled:

1. The physician must have had experience with it and be familiar with its pharmacologic action.
2. Antidotes such as neostigmine and ephedrine should be ready for immediate use.
3. Apparatus for maintaining an adequate airway, including endotracheal equipment and oxygen, should be available, and the physician should be skilled in its employment.

SCOTT M. SMITH, M.D., Salt Lake City.

Director of anesthesiology, University of
Utah Medical School.

CALAMINE AND ZINC OXIDE

To the Editor:—Capt. Paul A. Newton continues an ancient error in his communication on vesicopustular eczema (*THE JOURNAL*, September 8, p. 150). Referring to treatment, he mentions calamine lotion being used on the body surfaces and zinc oxide applied to the lesions of the axillas.

Calamine is zinc oxide plus some iron rust. Calamine has no virtues over zinc oxide, and many disadvantages. It would be best if calamine were removed from professional medicine. Neocalamine is a slight improvement in color but is still essentially zinc oxide. The rationale of application of zinc oxide to the human integument is the same as its rationale in utilization in wall paint—to cover.

Zinc oxide may be safely substituted for its colored form calamine or neocalamine in all formulas for the skin.

HERMAN GOODMAN, M.D., New York.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Incidence of Embolic or Thrombotic Processes During Immediate Convalescence from Acute Myocardial Infarction R. M. Nay and A. R. Barnes—p. 65.
*Case of Infection with *Brucella suis*, Causing Endocarditis and Nephritis; Death from Rupture of Mycotic Aneurysm E. L. DeGowin, J. R. Carter and I. H. Borts—p. 77.

Interventricular Septal Defect in Mother and Fetus.—Tucker and Kinney observed identical congenital cardiac lesions in a 20 year old mother and in her 6 months fetus. In each instance the lesion was a defect in the interventricular wall (Roger's disease) occurring at the base of the heart in the so-called undefended space. This lesion was diagnosed during life in the mother and proved by necropsy, while the lesion in the infant was demonstrated at necropsy. Heredity has often been mentioned as a possible factor, although few cases have been described as occurring in parent and offspring or in siblings. Further suggestive evidence that certain cases of congenital heart disease are due to inherent defects in the germ plasma is the not uncommon association of other congenital defects with congenital cardiac abnormalities. In Vierordt's series of 700 cases of congenital heart disease there were 80 cases with associated anomalies, while in Abbott's series of 1,000 cases 188 had associated anomalies elsewhere in the body. It is quite possible that the paucity of reports of congenital heart disease occurring in succeeding generations is due to the fact that relatively few persons suffering from congenital heart disease reach an age at which reproduction normally occurs.

Embolic and Thrombotic Processes During Convalescence from Myocardial Infarction.—Nay and Barnes studied 100 consecutive cases of coronary occlusion encountered at the Mayo Clinic. The criteria for diagnosis included an attack of severe substernal pain accompanied by sweating, pallor, fall of blood pressure and sometimes by collapse. In all instances positive electrocardiographic evidence was present. When death occurred during the period of observation and necropsy was performed, the clinical diagnosis was substantiated. Only patients who had entered one of the hospitals in Rochester, Minn., within a few days of the acute attack and had remained for a period of at least two weeks, unless death occurred prior to the conclusion of that period, were included. Complications of a thrombotic or embolic nature occurred in 37 cases. In 4 the complication caused death and in 8 cases the complications were contributing factors in the death. A second myocardial infarction occurred in 15 cases, pulmonary

embolism occurred in 14 cases, cerebral thrombosis or embolism complicated 8, arterial occlusions were noted in 4, and thrombophlebitis complicated 7. Forty-six of the patients were known to have had normal blood pressure prior to the coronary occlusion and myocardial infarction. Ten of these had subsequent myocardial infarctions during the immediate convalescent period. Forty-two of the 100 patients had had hypertension prior to coronary occlusion, and 2 of these had subsequent myocardial infarctions during the immediate convalescent period. Eighty-seven per cent of the cases of second myocardial infarction and 87 per cent of the instances of cerebral vascular accidents occurred between the fourth and the twentieth day, and 86 per cent of the cases of thrombophlebitis occurred between the tenth and the sixteenth day, periods when the blood pressure of patients who have acute myocardial infarction has been demonstrated to be at lowest levels. Thirteen of the patients died: 2 of cerebral thrombosis, 1 of pulmonary embolism, 1 from a second myocardial infarction and 2 of congestive heart failure, in the other 7 the exact cause was not ascertained.

Infection with *Brucella suis*.—DeGowin and his associates report studies on a farmer, aged 45, who had *Brucella suis* bacteremia. The infection lasted about two hundred days, during which endocarditis and nephritis developed. He recovered from uremia, only to succumb to rupture of a mycotic aneurysm of the left femoral artery. Sulfonamide therapy and the administration of convalescent serum failed to influence the infection. The pooled serum was prepared from the blood of donors who had recovered from *Br. suis* bacteremia. Anatomic studies after death revealed ulceration and vegetation on a previously normal mitral valve. The specific nature of the lesions was proved, during life, by the repeated isolation of *Br. suis* in pure culture from the blood stream, and, after death, by obtaining pure cultures of *Br. suis* from the vegetations from the endocardium, the walls of the mycotic aneurysm and other tissues. The blood contained specific agglutinins, but the skin did not react to brucellergin intradermally. As far as the authors are aware, this is the first reported case in which ulcerative endocarditis has been proved, beyond doubt, to be due to *Br. suis*. It is the second reported instance in which rupture of a mycotic aneurysm due to *Br. suis* has caused death.

Treatment of Pulmonary Embolism.—Pilscher reports 5 cases in which accurate diagnosis of femoral vein thrombi was made largely through venography and in which satisfactory results were obtained by ligating and partially resecting the involved femoral vein. Three of the patients had suffered pulmonary emboli before the femoral vein ligation was performed. The diagnosis of femoral vein thrombosis, when it is not associated with obvious thrombophlebitis (and the cases not associated with obvious thrombophlebitis are the most dangerous from the point of view of pulmonary embolism), is often difficult to make because of the slight clinical symptoms. If the possibility is kept in mind the diagnosis can often be suspected

and the suspicion verified by venography. Treatment can then be instituted before a fatal pulmonary embolism occurs. The question of the relationship of edema of the leg to femoral vein thrombosis interested the author especially. He observed that severe edema was present only when there was definite thrombophlebitis in the peripheral veins and was slight or absent when there was a bland femoral thrombosis, even though the femoral vein was completely obstructed up to the saphenous junction. The contrast between the old and the new method of treatment is brought home forcibly when a patient who has had a near fatal pulmonary embolism is able to leave the hospital walking two weeks later. In addition to the removal of danger of further pulmonary emboli, the operation of ligation and partial resection of the femoral vein had a beneficial effect on associated thrombophlebitis, particularly in the prevention as well as the relief of associated peripheral edema.

Multiple Primary Carcinoma.—The subject of this report, a woman, aged 60, had four primary carcinomas: (1) a medullary carcinoma of the breast, (2) a postirradiation carcinoma in the scar of the chest wall, with recurrence, (3) a transitional cell carcinoma of the cervix and (4) a papillary adenocarcinoma of the rectum. All lesions differed histologically, and no lesion was a metastasis of another. A search of the literature by Goldman did not reveal other reports of four primary carcinomas in 1 patient.

Tissue Calcification and Renal Failure Following Vitamin D Therapy.—Danowski reports 2 cases of renal damage secondary to prolonged therapy with vitamin D. In 1 of these extensive calcification of soft tissues was demonstrable. The extensive destruction of bone evident in the wrists and right hip of 1 of the patients is an anomalous development in the natural course of atrophic arthritis. It suggests that the extensive intake of vitamin D together with a low intake of calcium and phosphorus produced disruption of the structure of the bone of the type reported in rats, with subsequent absorption of the injured bone. During the first five of the six years of therapy the patient did not drink milk nor did she receive supplementary calcium. In the last year she took one or two glasses of milk daily during a period of one month. No clear principle has been formulated for a rational use of vitamin D in arthritis. Its introduction followed the chance finding that patients receiving this vitamin for allergic conditions experienced a coincident improvement in arthritis. It has been shown in rats that vitamin D may produce either an increase or a decrease in the bone ash. Clinically, improvement in arthritis during administration of vitamin D is not correlated with any consistent alteration in the density of the skeleton or of exostoses. In serial roentgenograms the osteoporosis may increase, decrease or remain unchanged. It seems that the favorable effects of vitamin D reported in arthritis are unrelated to the metabolism of calcium and phosphorus. The authors conclude that the therapy of arthritis with vitamin D demands careful supervision. The patient should never be permitted to continue treatment on his own initiative. Frequent determinations of the serum calcium with prompt reduction of dosage if hypercalcemia develops are essential. Repeated examinations of the urine and blood pressure must be made if renal complications are to be avoided.

Sulfadiazine in Pneumococcal Pneumonia.—Collen and Phillips determined the optimal dose of sulfadiazine through observations on 1,465 patients with pneumococcal pneumonia treated at the Permanente Foundation Hospital in Oakland, Calif. In the first half of this period 618 consecutive patients were treated with the usual doses of sulfadiazine, namely 5 Gm. initially and 2 Gm. every six hours thereafter, an average blood level of 8 to 10 mg. per hundred cubic centimeters being maintained. In the second half of this period 748 consecutive patients with pneumococcal pneumonia were treated with double doses of sulfadiazine. The majority of patients in the group receiving the double dose received 5 Gm. of sodium sulfadiazine in 500 cc. of sixth molar sodium lactate solution (pH 7.0 to 7.2) intravenously and 5 Gm. of sulfadiazine orally (total 10 Gm.) initially followed by 4 Gm. of sulfadiazine orally every six hours thereafter, an average blood concentration of sulfadiazine of 12 to 20 mg. being maintained. The two groups of patients had pneumococcal pneumonia of comparable severity. Adjuvant therapy, including the use of specific pneumococcus serum, was similar in the two groups. The treatment of patients with pneumococcal pneumonia with double doses of sulfadiazine resulted in a decrease in the gross mortality from 10.7 to 6.2 per cent; a decrease in the incidence of sterile pleural effusions from 5.2 to 2.7 per cent and a decrease in the average number of days in the hospital required for recovery (66 per cent required less than seven days, as compared to 45 per cent). There was no greater incidence of drug toxicity in patients treated with double doses of sulfadiazine than in those treated with usual doses. The authors conclude that for severely ill adult patients with pneumococcal pneumonia sufficiently large doses of sulfadiazine should be administered to maintain blood concentrations of at least 15 mg., with the optimal blood levels maintained preferably at about 20 mg. of sulfadiazine per hundred cubic centimeters.

Mixed Tumors of Salivary Glands.—Hellwig discusses observations on 82 primary tumors of salivary glands that have been studied during the last twenty years in the laboratory of the St. Francis Hospital, Wichita, Kan., among 4,352 cancers. The average age of the patients with mixed tumors was 38.4

years. More women were operated on for mixed tumors and more men for true cancers of the salivary glands. Sixty-eight tumors were located in the parotid glands, 12 in the submaxillary glands, 3 in the palate and none in the sublingual glands. Histologically, 51 of the 82 tumors were of mixed tumor type, 16 were of the adenomatous type, 8 presented combinations of these two types and 7 were true cancers. The salient feature of mixed tumors is the transformation of epithelial cells into myxochondroid tissue. The origin of tumor cells which can appear as of epithelial and again as of mesenchymal nature is not satisfactorily explained by the three current theories of the histogenesis of the mixed tumors of the salivary glands. From embryologic, histologic and topographic studies it is concluded that mixed tumors of the salivary glands are derived from misplaced elements of the notochord. This view would explain not only the complex structure of mixed tumors but also the striking predilection of these tumors for the parotid glands.

Symptomatology of Early Schistosomiasis Japonica.—Thomas and Gage report observations on 41 patients infected with schistosomiasis following the invasion of Leyte Island. All were studied within three months of their first infection. In 4 of these cases a history of burning and itching immediately after exposure was obtained. Symptoms which appeared between the third and ninth weeks were chills, fever, sweats, headache, backache, nonproductive cough, abdominal discomfort and profound anorexia. Urticaria accompanied these symptoms in one fourth of the cases and diarrhea in one fifth. The temperature was usually low in the morning and higher in the afternoon, reaching from 99 to 105 F. There was leukocytosis which rose from day to day, reaching a count as high as 50,000. Eosinophilia was present, at first to the extent of 15 to 20 per cent, later rising rapidly, reaching 50, 70 and, in a few cases, 90 per cent. The total number of eosinophils was often as high as 20,000. In 1 case 86 per cent of 54,400 white blood cells or 44,700 eosinophils were recorded. Patients varied from being practically asymptomatic to being extremely ill. Those with high fever sweat profusely, especially at night. They found it difficult to take nourishment and complained of severe headache, abdominal distention and cramps, and tenderness over the liver. Cough was troublesome and was often worse at night. The authors describe 2 cases which illustrate the course of schistosomiasis. Chemotherapy consisted of antimony and potassium tartrate in some instances and fuadin in others. No untoward reactions to fuadin were noticed. The commonest side effect of the antimony and potassium tartrate was nausea. Symptoms were promptly relieved in most cases, and eggs disappeared from the stools at least temporarily in many instances.

Mycotic Infections of Feet Among Soldiers. F. A. Dolce—p. 152.

Treatment of Human Bite Infections.—Henry describes 2 cases of human bite infection, both involving the right hand. All such wounds should be immediately cleansed well with soap and water, followed by gentle débridement. Dark field examinations and ten day anaerobic cultures are diagnostic aids. Tetanus antitoxin or a booster shot should be given. The wound should be irrigated with hydrogen peroxide and diluted solution of sodium hypochlorite. These wounds should never be sutured or repaired, but they should be left wide open and sprinkled with sulfonamide crystals. Hot magnesium sulfate or boric acid soaks should be applied daily for one week. The Wassermann and Kahn tests should be made and repeated one month from the time of the bite. Amputation should be avoided in the presence of an acute infection. Treatment should be conservative, and nature should be allowed to wall off the process. Bone involvement must be ascertained by x-ray at the time of injury and again later. Because rest aids the healing process, splinting is essential. Though penicillin has slight if any effect on certain mixed infections, a ten day treatment with penicillin would be indicated, 100,000 units being administered each day.

Hepatic Injury in Rats from Corn Meal Porridge and Sour Milk.—Gillman and his associates fed rats weighing 50 Gm on a diet of corn meal porridge and sour milk. At the end of fifteen months they had severe liver damage manifesting itself as a diffuse fatty liver, cirrhosis, lobular absorption or diffuse lobular enlargement. One or more of these pathologic processes may be present in the same liver. Biopsies of the livers of these rats, performed at frequent intervals, revealed that fat appears in the liver cells at the end of fourteen days and increases steadily until, after two hundred and fifty days, the liver is diffusely enlarged as the result of the accumulation of single large fat globules in almost all the liver cells. At this stage the sinusoids are for the most part closed, and the liver is relatively avascular. Thereafter secondary changes may occur leading to the absorption or diffuse enlargement of entire lobes or to nodular cirrhosis. It appears that the hepatic parenchyma and the interstitial tissue react independently of each other to the dietary injury. Cirrhosis is not a necessary sequel to hepatocellular damage, and whole lobes of the liver may be absorbed without stimulation of the connective tissue elements. In the development of the liver lesions there are two distinct phases. The first manifests itself as a diffuse accumulation of fat in the liver cells and the second as a vascular change, which may culminate in complete lobular absorption or may be associated predominantly with a fibrous tissue reaction with or without the regeneration of liver cells. A long standing fatty liver does not necessarily culminate in cirrhosis or lobular absorption. The absorption of an entire lobe implies a complete suppression of the reparative powers of the liver, together with the inhibition of some factor essential for the survival of the parenchyma and interstitium. Animals weighing over 100 Gm are resistant to the effects of this diet as compared with younger animals (50 Gm.). On this diet growth is apparently an essential factor for the development of liver damage.

Hemopoiesis in Pernicious Anemia.—Japa studied hemopoiesis in a woman aged 65 with typical pernicious anemia. Three specimens of sternal marrow were obtained by the usual technic—one before treatment, the second at the peak of the reticulocyte response on the sixth day after the parenteral administration of the liver extract and the third four weeks later, when considerable improvement in the peripheral blood count had taken place. The pathologic changes observed affect all three cell systems of the bone marrow and are in each of them of the same essential character. The analysis of the process of mitosis shows that the essential abnormality of hemopoiesis in pernicious anemia is the inhibition of the cell capacity for division, resulting in the prolonged duration of mitosis, its decreased frequency and earlier cessation, with consequent differentiation at an earlier genalogic stage. These changes seem to be closely connected with the lack of the proper development of the nucleoli and possibly some pathologic changes in the nucleic acids metabolism induced by the insufficient supply of the hemopoietic principle.

Digestibility of Phytate P of Oatmeal.—Cruickshank and his associates report observations on 4 adult subjects consuming a diet rich in oatmeal. They found that the phytate P of oatmeal was almost completely digested by the 4 adult subjects when the calcium intake approached requirement, and the P of the hydrolyzed phytic acid was absorbed from the intestine. Addition of calcium to the diet decreased the digestibility of phytate P if the supplementary calcium was taken together with the oatmeal and not if it was taken separately.

*Positive Influence of Water Supply on Health. Margaret M. Murray and D. C. Wilson—p. 23.

Late Bone Lesions in Caisson Disease.—In 1931 a submarine sank in 120 feet of water. Five of the crew escaped and survived, using the Davis apparatus. They all suffered in varying degree from the "bends" immediately or shortly after arriving at the surface. Before escaping they had to wait while the compartment was filled with water to equalize the pressures outside and inside the vessel. When these pressures were equal, a hatch could be opened outward to allow the men to rise to the surface. Two men escaped after two and one-half hours under this increasing pressure and the rest after three hours. No recompression treatment was performed. When examined twelve years after the accident 3 of the 5 survivors showed bone lesions; the other 2 survivors could not be traced. In 1 of the 3 the bone lesions were much more severe, probably because this man made strenuous efforts to open a stopcock. In radiologic examination all 3 men showed small rounded areas of rarefaction surrounded by a thin shell of hypercalcification in the end of the long bones, confirming the pathology of infarction followed by aseptic necrosis and incomplete repair. In the severe case the heads of both femurs had partially collapsed, resulting in osteoarthritis deformans. The exact cause of infarction is not known.

Influence of Water Supply on Health.—Recent research has emphasized the health aspects of three minerals found in water: calcium, iodine and fluorine. Lack of calcium may interfere with calcification of bones and teeth; lack of iodine may lead to enlargement of the thyroid gland; lack of fluorine may favor the development of dental caries. Murray and Wilson point out that in Britain the Water Act, which received the royal assent on June 15, 1945, will impose on the minister of health for the first time the duty of promoting the provision of a water supply adequate for all reasonable needs of house-

holders. To meet the "reasonable needs of householders for water," as is mentioned in the Water Act, the health and environmental aspects of a water supply should be taken into account. By comparing the water supply conditions in two villages, the authors show that water schemes cannot be planned efficiently on a village basis and that in some districts it may be necessary to employ alternative supplies calculated to give a water of desirable mineral content, or even a mixture from several sources, in order to meet both health and nutritional requirements. Such adjustments in composition will not ensure an adequate supply in every household, because there may be environmental reasons which prevent the proper utilization of the water supplied.

Serologic Diagnosis of Typhus.—Wolstenholme and Gear evaluate the serologic tests for the laboratory diagnosis of typhus. They regard the Weil-Felix test as the most reliable and describe the agglutination of the various strains of *Proteus* used in epidemic typhus, murine typhus and tick bite fever. This test does not distinguish between epidemic and murine typhus, and sometimes either of these forms of typhus from tick bite fever. "Bedside" or "field" tests for the diagnosis of typhus are described, and it is noted that under South African conditions the most valuable of these is a modification of the method of Castaneda and Silva. The results have been found to agree very closely with those given by the standard Weil-Felix test. This test also does not differentiate between the various forms of typhus found in South Africa. Such differentiation is possible in most cases by means of the rickettsial complement fixation tests. The rickettsial complement fixation test is a reliable serologic test for the diagnosis of typhus and of tick bite fever. In most cases it is possible by means of this test to distinguish between epidemic typhus and murine typhus, and between these two forms of typhus and the variety of tick bite fever occurring in South Africa. The rickettsial complement fixation is thus a valuable additional serologic test for the diagnosis of typhus.

Survival of Transfused Erythrocytes of Stored Blood.—Altmann and Watson point out that sodium citrate alone as an anticoagulant is not wholly satisfactory in that the survival time of the transfused erythrocytes is shortened. The addition of dextrose prolongs the useful storage period in that survival is satisfactory after storage from fourteen to twenty days, but dextrose cannot be autoclaved with sodium citrate, as it caramelizes at high temperatures in an alkaline medium. A sodium citrate-citric acid-dextrose mixture of pH 4.8 to 5.0 does not show caramelization of the dextrose after autoclaving. Blood stored in this mixture remains suitable for transfusion, as far as the *in vivo* survival of the transfused red cells is concerned, for a period up to twenty-one days. Blood stored for periods up to fifteen days in sodium citrate-citric acid-glucose solution gives *in vivo* survival of the transfused erythrocytes identical to fresh blood. Blood stored for twenty-one days still remains satisfactory, and even blood stored for twenty-eight days can be used with benefit to the patient. Blood should not be stored for more than twenty-one days as a routine. Except for the hemorrhagic states and other clinical conditions which require fresh blood, blood stored by this method can be used in all cases in which transfusion is indicated.

*Digestive Allergy: Sensitization to a Decomposition Product of Food Protein. P. Blamontier.—p. 162.
Disregarded Cause of Undulant Fever. P. Lesbre.—p. 162.

Carotid Sinus and Retinal Circulation.—Riser and his associates report observations on 50 subjects in whom they determined simultaneously the retinal arterial tension and the general arterial tension, while performing various manipulations on the carotid sinus, such as digital compression of the sinus region, inhibition of the sinus by procaine hydrochloride and compression of the carotid artery below the sinus. They stress that the variations provoked in the general and the retinal arterial tensions by excitation of the carotid sinus are always synchronous and of the same amplitude. There never appeared a direct action of the sinus on the retinal circulation that could be separated from the action on the general circulation.

Sensitization to Decomposition Product of Food Protein.—Blamontier points out that, when sensitization takes place by the respiratory route, the cutaneous reactions with the offending substance are nearly always positive. This is not the case in anaphylaxis of digestive origin. A certain protein, such as that of eggs, meat or milk, may elicit an urticarial crisis every time it is ingested and the skin reaction with the substance may nevertheless remain constantly negative. The author together with Pasteur Vallery-Radot had the idea that such subjects are sensitized not to the ingested protein but to a decomposition product of this protein which develops in the course of digestion. He describes studies on a patient aged 34 who for about ten years had had attacks of generalized urticaria with Quincke's edema of the face every time he ate lamb or mutton. The attack appeared five to six hours after the meat had been ingested. All skin tests with lamb or mutton were negative. Even samples incubated with gastric or with duodenal juice produced negative results. However, when specimens of the meat were incubated with both gastric and duodenal juice a positive skin reaction was finally obtained. A Prausnitz-Küstner test with this liquid was likewise positive. The positive outcome of these two tests convinced the author that the patient was sensitized to a product of the digestion of the meat rather than to the meat itself.

Giornale di Medicina, Palermo

2:342-398 (April-May) 1945. Partial Index

- *Nitrogen Determination by the Kjeldahl Method. S. Sorce.—p. 353.
Epinephrine Therapy (Ascoli's) in Pernicious Malaria. F. Sendler.—p. 362.

Kjeldahl Method for Determination of Nitrogen.—Sorce made simultaneous determinations of the amount of nitrogen in the blood and in the urine of 10 normal adults and 10 diabetic patients by the wet (Kjeldahl) and the dry (Dumas) methods. In both groups the nitrogen values in the urine and in the blood were higher when the dry method was used. In normal persons the differences with the dry method varied between 2.06 and 5.67 per hundred cubic centimeters of urine and between 4.16 and 12.50 per hundred cubic centimeters of blood. In diabetic patients with hyperglycemia and glycosuria and before administration of any therapy the differences of excess were of 2.70 per hundred cubic centimeters of urine and of 37.77 per hundred cubic centimeters of blood. The nitrogen values in the urine and in the blood returned to normal as glycemia was lowered and glycosuria disappeared on correct insulin and diet therapy. Before treatment was begun there was no relation between the degree of hyperglycemia and glycosuria and the nitrogen values in the urine and in the blood. The author points out that in diabetes, especially in severe forms of the disease, nitrogen bodies, which cannot be determined by the Kjeldahl method, increase in the blood up to figures over 30 per cent. The increase is due to metabolic disorders of nitrogen, which are severe in the grave forms of the disease. An expression of the disorder is manifested by azoturia and aminoaciduria, which in many diabetic patients reaches figures twice those of normal urinary excretion of nitrogen.

Book Notices

The History of Surgical Anesthesia. By Thomas E. Keys. With an Introductory Essay by Chauncey D. Leake, and a concluding chapter The Future of Anaesthesia by Noel A. Gillespie. Cloth. Price, \$6. Pp. 191, with 43 illustrations. New York: Schuman's, 1945.

The author of this book has become a real authority on the subject of the history of surgical anesthesia. He has been trained as a librarian, and he has learned to make proper evaluation of printed matter. He has written on the subject of the history of anesthesia repeatedly over a period of years, and his work has received the approbation of those who are keenly interested in the subject of medical history. He is therefore most competent to prepare such a book as this one.

The form of the book is one that lends itself to easy understanding because the volume is not too large, it is well printed on good paper and it is thoroughly illustrated and annotated. The purpose of the author was to discuss the subject not from the view of controversy on the point of who should have priority for a given thing but simply to present the facts as they appear in the existing literature. The subject has been covered in a brief but general way so that as many things as possible might be touched on without going into great detail on any one of them.

Presentation of the subject is most satisfactory. The author has made clear in his preface what he planned to do and some of the story of why he did it. He was most fortunate to have obtained an introductory essay by Dr. Chauncey D. Leake, dean of the Medical School of the University of Texas. It indicates very well Dr. Leake's long and keen interest in the subject of anesthesia. The story of anesthesia is then printed and illustrated in pages 3 to 92 and is followed by a bibliography running from pages 93 to 102 that indicates the original sources of material. In the second section, pages 103 to 118, is a chronology of events relating to anesthesiology and allied subjects which is similar to the one that the author prepared for "Clinical Anesthesia." From pages 119 to 125 is the bibliography relating to the chronology table. The third section is presented from pages 126 to 169, and includes a comprehensive bibliography. It could be well called "suggested reading" for those who would like to know in detail the history and progress of the development of anesthesiology. "The Future of Anaesthesia" has been prepared by Noel A. Gillespie and runs from pages 170 to 175. It presents his idea of that subject. In an appendix Dr. John F. Fulton has allowed the use of the material at his disposal concerning Morton and some early literature on ether. The index is easy to use and extends from pages 183 to 191.

It would appear that all of the statements in this book are defensible and most of them are documented. There is no doubt that the material is accurate.

There can be no doubt that this is the best and most thorough presentation of the history of surgical anesthesia that has yet been written.

The Bacterial Cell in Its Relation to Problems of Virulence, Immunity and Chemotherapy. By René J. Dubos, George Fabian Professor of Comparative Pathology and Professor of Tropical Medicine, Schools of Medicine and Public Health, Harvard University, Boston, Mass. With an Addendum by C. F. Robinow. Harvard University Monograph in Medicine and Public Health No. 6. Cloth. Price, \$5. Pp. 460, with 13 illustrations. Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1945.

Knowledge of cellular immunology has lagged in development behind cellular pathology. Summarizing and integrating presentations in book form of what is known of cellular immunology have been scarce and inadequate. This monograph is a timely and much needed contribution. Dubos has succeeded admirably in blending in organic fashion results of widely scattered biochemical, physical and immunologic studies. An introductory chapter deals with problems, materials and methods. The subjects of cytology of bacteria and their physicochemical and staining properties, cellular structure, variability, virulence, immunization against bacterial infection, and bacteriostatic and bactericidal agents are treated in separate chapters. The concluding chapter, on trends and perspectives, is stimulating in its philosophical vein. Wisely selected quotations at the begin-

ning of each chapter introduce a broad contemplative element and add much to the readability. There is an appendix by Robinow on the nuclear apparatus and cell structure of rod-shaped bacteria. The presentation is lucid, complete and up to date. There are seventy-one pages of bibliography. In the German titles the nouns have not been capitalized. This book is warmly recommended to all interested in bacteriology and immunology.

The New-Born Infant: A Manual of Obstetrical Pediatrics. By Emerson L. Stone, M.D., Associate Clinical Professor of Obstetrics and Gynecology, School of Medicine, Yale University, New Haven, Conn. Third edition. Cloth. Price, \$3.25. Pp. 314. Philadelphia: Lea & Febiger, 1945.

The book, as the author states, has two aims: to correlate and arrange in orderly fashion a mass of data that is otherwise scattered through a vast medical literature and to emphasize at every possible opportunity the obstetrician's point of view and responsibility to sharpen and extend his interest in this important branch of his work. This it does in an unusually interesting manner. The book covers every phase of the newborn period in a clear, simple and accurate manner, discussing methods of prevention, diagnosis and treatment of the many problems of this period. The work is a credit to the obstetrician and stimulates interest in the baby at a time when quick, intelligent care is so important and so frequently neglected. Every obstetrician, general practitioner and pediatrician should have the book.

Proceedings of the Institute on Readjusting with the Returning Servicemen. Held March 8-9, 1945, in The Knickerbocker Hotel, Chicago, Illinois Under the Auspices of the Illinois Society for Mental Hygiene. Paper. Price, \$1.25. Pp. 156. Chicago: The Society, 1945.

This book presents the proceedings of a two day institute held in Chicago in March under the auspices of the Illinois Society for Mental Hygiene. It includes the round table discussions and papers read at the conference. The material essentially relates to the psychologic and psychiatric aspects of problems of readjustment to civilian life, with emphasis on postwar educational and vocational needs and the personal relationships involved in family life. An optimistic note is sounded by some of the speakers in recognizing the benefit of military training and experiences in strengthening many men for orientation of attitudes essential for civilian adjustment. There is also stressed the need for friendliness and expressions of genuine interest to the returning veteran from all those at home with whom he will have dealings. This is a timely book, representative of the thinking and plans of a group of people closely concerned with the readjustment of the veteran.

Secretaría de salubridad y asistencia, memoria 1943-1944, basada en el informe de labores. Presentado al H. ejecutivo de la Unión. Por el Dr. Gustavo Baz, secretario del ramo. Paper. Pp. 420, with illustrations. Mexico, D. F., [n. d.].

This book is based on the report of Dr. Baz to the executive government of Mexico. Dr. Baz is the secretary of the Mexican Secretariat of Sanitation and Assistance, the national department which was created from the fusion of the Secretariat of Public Assistance and the Department of Public Health. The report is concerned with the work on public health, sanitation and public assistance as carried on by the department from Sept. 1, 1943, when it began to function, up to Aug. 31, 1944. The author in the introduction outlines the purpose of the work of the actual government and of his department, which is to care for the Mexican population in all the fields of health, sanitation and education. The book contains several chapters showing (1) the development of hospitals through the country, (2) the better training of technicians in these fields and the international exchange of technicians and (3) a report on work carried on in sanitation, epidemiology, hygiene, nutrition, care of infants and children, vaccination, prevention of tuberculosis and prevention and therapy of venereal diseases and tropical diseases. The functions and work carried on by the various departments of the secretariat in the various states of Mexico are described in detail. The hospitals, polyclinics, crèches and many centers for giving health care to the people are excellent in all respects, as shown by the pictures. The book vividly shows the importance given to public health and public assistance in Mexico by its government.

Queries and Minor Notes

THE ANSWERS WERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ACUTE NEPHRITIS IN CHILD

To the Editor:—A 7 year old girl came down with acute nephritis March 23, 1945 with a nonprotein nitrogen count of over 100, and the urine loaded with red blood cells. Concomitant acute mastoiditis cleared up with penicillin. The urinary findings have improved steadily, so that at present only a plus minus albumin remains. Urine studies are done weekly. Should a change of climate from Pittsburgh be considered for the coming winter? Please name a few general localities in the continental United States where the climate would be of value in prophylaxis against development of chronic nephritis by keeping upper respiratory infections to a minimum.

Captain, M. C., A. U. S.

ANSWER.—It is to be hoped that the child received sufficient penicillin to destroy the infecting organisms completely, for there exists a definite hazard in the possibility of developing resistant strains which then would not yield to penicillin therapy in the future. It is well known that upper respiratory infections are much less frequent in the Southern states and particularly in the Arizona, New Mexico, Colorado area. Chilling, smoke and dusts are predisposing factors to acute respiratory infections; avoidance of these is desirable. Florida, the Gulf Coast or southern Texas is less desirable for a patient such as the one described because of the greater heat and the high atmospheric humidity, which make for excessive perspiration and therefore handicap the repair of the kidneys by depriving them of water needed for diuresis. In this regard it should not be forgotten that it is less work for the kidneys to secrete a larger volume of dilute urine than a small volume of highly concentrated urine. It is sound physiologic therapy to reduce the functional burden of injured structures as much as is feasible. An evaluation of the renal functional capacity with a recheck every six months is desirable. The renal concentration test is probably the most sensitive index of early depreciation in functional reserves. The urea concentration test, though less valuable in the milder instances of renal injury, should be included also, for it yields quantitative results which can be readily contrasted as tests are repeated. Repeated observation of the condition of the blood is important in any patient with nephritis; effective repair of injured tissues cannot be expected if they do not receive adequate oxygen because of an anemia. Even relatively minor degrees of anemia are significant. Such factors are probably more important than climate in the prophylaxis of chronic nephritis.

MYALGIA AND ALTITUDE

To the Editor:—In the New York Post Charles Van Devander in his column "Washington Memo" tells about many of the delegates to the Inter-American conference in Mexico City being ill with what he says is known as mountain sickness for want of a better name. I was particularly interested in one of the symptoms of this illness noted by this writer, namely an ache in the limbs, and I was attracted by his explanation that it is due to the high altitude of Mexico City and the consequent decrease of oxygen content of the air. If this explanation is correct, this so-called mountain sickness would be a concrete illustration to substantiate the thesis that anoxia is one cause for myalgia. If this is so, fliers or high altitudes should experience pain in their limbs. Do people not accustomed to high altitudes suffer muscle pains when suddenly brought into rarefied atmospheres? Is the concept of anoxia as the cause of myalgias at high altitudes correct? Are there references to this problem? If anoxia resulting from decrease in oxygen content of the air may produce myalgias, then cannot anoxia due to other causes, especially disturbances in physiology, cause myalgias in people living at sea level? My interest is mainly with the last query, and it is this which attracted my attention to Van Devander's discussion on mountain sickness. If it is true that high altitudes cause anoxia and that this in turn causes muscle pains, is it proper to reason that muscle pains in people living in low altitudes may also be caused by an anoxia? May anoxia be one explanation for myalgias in these people? Is there positive scientific proof of the latter, assuming, of course, that such a thesis is tenable in the first place?

Harry Weiner, M.D., Brooklyn.

ANSWER.—This inquiry boils down to a search for opinion as to a common cause for the myalgias seen at ordinary altitudes and for aching limbs as described in visitors recently arrived at Mexico City (7,500 feet above sea level). There is abundant literature in standard textbooks of physiology, such as Best and Taylor or Macleod, indexed under mountain sickness. However, the lowest level given for this complaint is 10,000 feet, and among the many symptoms listed aching limbs and pain are not included. For a better consideration of pain

which is more satisfying to the mind than is the usual discourse on myalgia the recent textbook by Sir Thomas Lewis entitled Pain (New York, Macmillan Company, 1942) is suggested. There, in a somewhat philosophic discussion of muscle pain, a distinction is made between muscle ischemia, which is regional and may cause pain, and anoxemia, which is general and causes brain and heart symptoms but not myalgia. Fliers at high altitudes do have pain in the limbs. Pain in that instance is caused by lowered barometric pressure and not by anoxia. This fact has been proved in many chamber "flights" by experimental teams and by the air corps in trainees in similar manner. Aviators' bends never occur at 7,500 feet and seldom if ever below 20,000 feet. If myalgia is caused by anoxia the mechanism must be impaired blood flow to the individual muscle and not deficient respiration.

CONTINUED FEVER FOLLOWING SCARLET FEVER

To the Editor:—I should like your opinion as to the necessity of enforcing bed rest for scarlet fever patients after they have apparently made a good recovery except for a fluctuating temperature from 98.6 to 99.6 F. During the past winter I have had several scarlet fever patients who, months after the original condition has cleared, continue to have a slight fever. In none was there involvement of the lymphatics, ears, kidneys or heart, yet their sedimentation rates were about twice the normal rate.

Joseph P. Griffin, M.D., Chesterton, Ind.

ANSWER.—With the mild type of scarlet fever which now generally prevails, enforced bed rest of ten days is sufficient if there are no complications. In some contagious disease hospitals the minimum requirement of enforced bed rest is fourteen days from the onset of the illness. However, it is best to confine patients with elevated temperatures to their beds regardless of the duration of the disease. Often, if there is a rise in the erythrocyte sedimentation rate about the fourteenth day of scarlet fever, it is assumed that some complication is present or will develop. In patients in whom there is not any involvement of the lymphatics, ears, kidneys or heart, a sinusitis should be suspected if the throat, including the tonsils, is negative.

ALOPECIA

To the Editor:—What are the prognosis and effective therapy, if any, for alopecia of the head, eyebrows and eyelashes which has gradually become complete during the past year in a normal 17 year old boy. He has normal distribution of the axillary and pubic hair.

George D. Burns, M.D., Derby, Conn.

ANSWER.—This is undoubtedly a case of alopecia areata, which from the description may go on to that known as alopecia totalis. The prognosis depends chiefly on the amount of hair loss and the age. If the alopecia is partial, the prognosis is, of course, much better and roughly parallels the amount. The youth of the patient tends to make the prognosis more favorable. As far as is known, the distribution of hair dependent on sex has nothing to do with alopecia areata.

There are many forms of treatment. X-rays to the scalp short of producing an erythema are said to be effective; these should be given by an expert, of course, because of the hazard of producing a permanent alopecia due to overdosage. Filtered x-rays may be used to the cervical spinal cord. Ultraviolet ray therapy is one of the most effective methods; it should be used in graduated doses, and some attempt should be made at using stimulating quantities. Recommended agents for local application to the scalp are both numerous and varied, but in general they have irritant properties. One is liquefied phenol, which is quickly neutralized by alcohol as soon as the treated area develops a parboiled appearance. Another popular agent is Cutler's fluid, which consists of equal parts of tincture of iodine, phenol and chloral hydrate. This is applied to all the parts and repeated on the average of once a week, or as soon as the irritation subsides. It is probable that this disease tends to run a course which in most cases is self limited. In the malignant variety the hair continues to fall until a total alopecia results, and this is permanent. In total alopecia the loss of hair may not be total, although some alopecia remains permanently.

MULTIPLE IMMUNIZATION DURING PREGNANCY

To the Editor:—A woman aged 27, due to be delivered in December, plans to fly to a destination outside the country to rejoin her husband. This is the first pregnancy and her condition is excellent. Before her passports will be issued she is required to have all immunization inoculations including that for typhus. Are there any untoward sequelae to be anticipated? Are any special precautions to be observed?

John M. Higgins, M.D., Sayre, Pa.

ANSWER.—No untoward sequelae are to be anticipated from immunization inoculations, including typhus, given during pregnancy. No special precautions need be observed in giving these inoculations.

PROGNOSIS OF SUBARACHNOID HEMORRHAGE

AND ITS RELATION TO LONG TERM MANAGEMENT

GEORGE A. WOLF JR., M.D.

HELEN GOODELL, B.S.

AND

HAROLD G. WOLFF, M.D.

NEW YORK

Following the definition of the syndrome of subarachnoid hemorrhage by Symonds¹ in 1923, its recognition has presented little difficulty. Excellent descriptions of the syndrome and summaries of the literature have been presented by Strauss, Globus and Ginsburg,² Sands³ and Dandy.⁴

Subarachnoid hemorrhage is responsible for 2 per cent of sudden deaths.⁵ It comprises 7 per cent of all cerebral vascular disease and approximates in frequency parenchymatous cerebral hemorrhage (8 per cent).⁶ The most common cause of subarachnoid hemorrhage is rupture of intracranial arterial aneurysms. Among others the studies of Bremer,⁷ Forbus,⁸ McDonald and Korb,⁹ Richardson and Hyland¹⁰ and Magee¹¹ have contributed much to our knowledge of the formation, occurrence and natural history of intracranial arterial aneurysms and their role in the production of subarachnoid hemorrhage. Dandy⁴ has recently reported his pioneer work in the surgical treatment of intracranial arterial aneurysms.

A review of the available information in the literature and the study of additional patients from the New York Hospital has been undertaken with the aim of ascertaining the prognosis and formulating the long term management of patients with subarachnoid hemorrhage.

INCIDENCE ACCORDING TO AGE AND SEX

Forty-six patients at the New York Hospital with subarachnoid hemorrhage are being studied. Postmortem evidence of subarachnoid hemorrhage, operative visualization or xanthochromic cerebrospinal fluid with blood demonstrated by lumbar puncture were the criteria for inclusion. Neonatal and traumatic hemorrhages have not been included.¹²

There were 23 females and 23 males. The age distribution is given in table 1. Age and sex distribution were essentially similar to that reported by McDonald and Korb.⁹

"RECURRENT HEADACHES," "MIGRAINE" AND SUBARACHNOID HEMORRHAGE

Seven (15 per cent) of the New York Hospital patients had definite migraine, and 12 (26 per cent) had periodic, recurrent headaches both unilateral and bilateral, for many years. The incidence of "frequent and severe" headaches of all types in a cross section of the healthy population has been found to be 9 per cent.¹³ Migraine and "recurrent headaches" of many years' standing occur in from 10 to 41 per cent of persons with subarachnoid hemorrhage and aneurysm (Goldflam,¹⁴ Richardson and Hyland,¹⁰ New York Hospital series and Magee¹¹).

Adie¹⁵ and Dunning¹⁶ have postulated the occurrence in the course of migraine of small cranial vascular accidents associated with cerebral infarcts. It is possible that some of the patients considered here are in that category. No further information is available, and the matter has been dealt with extensively elsewhere.¹⁶

PRECIPITATING AND PREDISPOSING FACTORS

The majority of New York Hospital patients were engaged in ordinary activity when rupture took place. Two patients were having sexual intercourse when the attack occurred. Magee¹¹ and Richardson and Hyland¹⁰ have noted excessive activity to be associated with rupture only rarely.

One patient who died had cirrhosis of the liver with bleeding tendency, and 2 patients who lived had syphilis. No premonitory signs which could definitely be considered to precede bleeding were noted.

Five of the New York Hospital patients had elevated blood pressure and at least 3 had definite hypertensive

12. It is to be emphasized that this study is concerned with subarachnoid hemorrhage. Patients with aneurysms detected at operation and autopsy, but not associated with subarachnoid hemorrhage have not been included.

vascular disease. Sahs and Keil,¹⁷ Ohler and Hurwitz¹⁸ and Wilson, Rupp and Bartle¹⁹ report similar findings. Only 5 of the 30 patients who recovered had elevated blood pressure.

SYMPTOMS

The symptoms included sudden violent headache, dizziness and vertigo, vomiting, drowsiness, stupor and coma, stiff neck and pain in the back of the thighs and

legs, tightness of these areas, sweats and chills. Convulsions occurred in 17 per cent of the New York Hospital patients, in 9 per cent of Richardson and Hyland's¹⁰ and in 12 per cent of Magee's.¹¹ Low back pain was a striking feature in 3 patients, an observation previously reported by Savitsky and Strauss²⁰ and Magee.¹¹

Headache was fronto-occipital, fronto-ocular, fronto-temporal, occipital and sometimes generalized. It was described as a feeling of a sudden snap in the head followed by intense throbbing ache. Sudden onset of an extremely high intensity pain, chiefly in the back of the head, was most common. Not one of these symptoms was of any prognostic value.

SIGNS

The signs were fever, occasionally coming on twenty-four hours or more after the accident and lasting for over a week, stiff neck, Kernig sign, third nerve palsy, delirium, hemiparesis, other evidence of corticospinal tract disease and fundal hemorrhage. (This may be of value in localizing an aneurysm if found in only one eye.⁴ However, in 1 instance [New York Hospital series] a single hemorrhage in one eye was not associated with a demonstrable aneurysm, although subarachnoid hemorrhage was found.) In 2 instances when localizing signs were present an aneurysmal source of bleeding was not found at autopsy. No prognostic information could be gained from the signs. Many of the patients who fully recovered lost consciousness and had convulsions at the onset of the illness.

THE DEMONSTRATION OF CEREBRAL ANEURYSMS

Of the 18 New York Hospital patients with subarachnoid hemorrhages who died, 15 died as a result of subarachnoid hemorrhage, and postmortem examinations were done on 11. These examinations were carefully performed, but no special dissections were made. In 5 of these 11 aneurysms were demonstrated. The remaining 6 patients had subarachnoid hemorrhage with no demonstrable source of bleeding. One of the latter 6 had "cirrhosis of the liver with bleeding tendency." Four of the 5 patients with aneurysm had localizing signs during their illness due to cranial nerve, cerebral or fundal damage. One patient with localizing signs showed no source of bleeding at autopsy, and 3 patients

with localizing signs had negative arteriograms. In addition, aneurysms were surgically visualized in 5 patients with localizing signs and positive arteriograms. In short, in 16 patients with subarachnoid hemorrhage exposure of the cerebral vessels revealed aneurysms in 10.

Ayer⁵ states that autopsies on 14 patients with subarachnoid hemorrhage revealed aneurysms in 14. Magee¹¹ reported 43 instances of aneurysm in 58 post-mortem examinations on his patients with subarachnoid hemorrhage. Ohler and Hurwitz¹⁸ found no aneurysms in 5 postmortem examinations on their patients. Richardson and Hyland¹⁰ reported aneurysms in 27 of 33 autopsies on such patients.

When, in the presence of subarachnoid hemorrhage, localizing signs occur, an aneurysm is more likely to be found, but localizing signs do not make it certain that an aneurysm will be found. On the other hand, in none of the New York Hospital patients with aneurysm (who could be examined) were localizing signs absent.

ARTERIOGRAMS

Ekström and Lindgren²¹ found in 35 postmortem examinations on patients who had received thorotrast for cranial arteriography that 21 had thorotrast emboli in small vessels. In 6 of these cerebral infarction was evident. Peet and List,²² using thorotrast, had no accidents or sequelae after arteriography in a series of 38 patients over a two year period. Moreover, the later use of diodrast has not been associated with obvious complications, although postmortem studies have not been done. Local sensations and vasomotor reactions have occurred but have not been of serious proportions. Nine of the New York Hospital patients had arteriograms, and aneurysm was demonstrated in 5. Thirty-five per cent diodrast was used, and all of the arteriograms were done without mishap.

* One died two years later of a pulmonary infarct. One died within the first year after the initial hemorrhage, of unknown cause. One died three years later of unknown cause.
† Five years after first attack.

PROGNOSIS

Fifteen of the 46 patients of the New York Hospital series died as a direct result of the subarachnoid hemorrhage. One died two years later of a pulmonary infarct, 1 died within the first year of unknown cause, and 1 died three years later of unknown cause.

If will be seen from table 2 that of the 74 patients in Magee's and the New York Hospital series who had recurrences, 41 had them in the second to fourth week, and, of the 42 patients who died in recurrences, 28 died during this period.

Sequelae occurred in 19 of the 30 surviving New York Hospital patients, but evidence of gross structural neurologic disorder occurred in only 6. Magee¹¹ reports sequelae in 18 of 22 patients followed, but only 3 had evidence of gross structural neurologic disorder. Richardson and Hyland¹⁰ report "severe residual symptoms" in 8 of 37 followed patients. In short, about 20 per cent of patients with subarachnoid hemorrhage exhibit significant sequelae. Sustained, chronic or recurrent headache persisting longer than two months following rupture of intracranial aneurysm with subarachnoid hemorrhage is rare in the New York Hospital patients who did not have headaches before the accident.

The New York Hospital recurrence rate was higher than Magee's,¹¹ and the death rate (39 per cent) was lower than his (50 per cent). The New York Hospital death rate was also lower than that of Ayer's⁵ and of Ohler and Hurwitz's¹⁸ series (50 per cent). This may be explained by the fact that the New York Hospital has no ambulance service, and probably many of the patients who die in the first attack do not reach the hospital. The fact that only 5 of our patients died in the first attack supports this conception. Sahs and Keil¹⁷ reported that 18 of 64 patients (28 per cent) died and 41 of 120 of Sands's³ patients died (34 per cent). At present we cannot help those who die in the first attack but must direct our efforts toward the survivors in preventing death from recurrent attacks of bleeding.

The 196 patients in the series of Magee¹¹ and the New York Hospital may be divided into two groups. The first group comprises those who died in the first six months after the first attack of bleeding. Fifty-seven, or 29 per cent, of the patients died in the first attack and may be waived from further comment because they cannot be helped by present methods. Forty-one, or 21 per cent, may be helped by operative procedures. These patients died in recurrent attacks within one year after the initial hemorrhage. Twenty-eight, or 14 per cent, of the patients died during the second to fourth week after the first bleeding. Five per cent died between the fourth week and the end of the first year. Procedures aimed at helping the patients in the first group must be instituted before or soon after the second week if the 21 per cent who die in recurrent attacks are to be saved. After the fourth week 14 per cent will have already died.

The second group consists of 45 patients who survived the first six months after the first episode of bleeding. This constitutes 23 per cent of the patients. No information is available about the patients who were followed less than six months. The prognosis of this group is difficult to evaluate, because long follow-up facts are not available. Twenty-one of the New York Hospital series were alive at the end of follow-up periods of from six months to nine years, an average of 3.4 years follow-up. One patient died as the result of a pulmonary infarct two years after the first attack. One patient died during a second attack of ruptured aneurysm and subarachnoid hemorrhage five years after the first. One of the New York Hospital patients was alive seven years after the first attack. During this time he had had six recurrences. Another New York Hospital patient was alive and free from sequelae and recurrences

nine years after the first attack.^{22a} Magee¹¹ found 22 of his surviving patients living an average of fourteen months (six months to four years) after the first attack of bleeding (table 3). Richardson and Hyland¹⁰ followed 37 recovered patients an average of four years (six months to ten years) and found that all were alive except 2 who had died from unknown causes. Five of their patients had had nonfatal recurrences. Dandy⁴ reports 2 patients alive twenty-two and fifteen years after hemorrhages. But he found that 2 patients died from recurrences eleven and six years respectively after the first rupture. Jefferson²³ described 3 patients alive six, five and four years respectively after the initial hemorrhage. He also reported that 1 died from a second subarachnoid hemorrhage eighteen years after the first attack. Rosen and Kaufmann²⁴ reported a single patient who died of subarachnoid hemorrhage twenty-seven years after the original attack.

In brief, it would appear that patients who survive the first year have a good chance of relatively long

TABLE 3.—Results of Follow-Up

survival, but the threat of repeated hemorrhage is always present. Hence, if an aneurysm can be demonstrated in these patients (group 2), surgical intervention is justified.

MANAGEMENT

Suitable recommendations presented elsewhere have dealt with the important topics of pain and headache, restlessness and excitement, nourishment and fluid intake during the period immediately following hemorrhage.³ Discussion here will be focused on long term management gleaned from our growing knowledge of prognosis. From the facts that have been presented it is evident that, if patients with subarachnoid hemorrhage could be treated effectively and safely by surgical procedures in the first two weeks after the hemorrhage, the threat of recurrent hemorrhage and death in approximately 70 per cent of all patients with subarachnoid hemorrhage could be removed.

The surgical treatment of subarachnoid hemorrhage as such has been considered only briefly in the literature. Relevant to this problem, however, are the studies of Dandy⁴ on intracranial aneurysm, as the rupture of these aneurysms is the most common cause of subarachnoid hemorrhage. Dandy reported a 25 per cent mortality in the treatment of intracranial aneurysms by surgery. That is, he did thirty-six operations and obtained twenty "cures" for a variable follow-up period. A review of Dandy's 108 protocols of patients with intracranial cerebral aneurysms reveals information

22a. Since the preparation of the manuscript, another New York Hospital patient was found to be alive and well after having had a subarachnoid hemorrhage twenty years previously.

23. Jefferson, G.: On the Sacular Aneurysms of the Internal Carotid Artery in the Cavernous Sinus, *Brit. J. Surg.* 26: 267, 1938.

24. Rosen, S. R., and Kaufmann, W.: Aneurysm of the Circle of Willis with Symptom-Free Interval of Twenty-Seven Years Between the Initial and Final Rupture, *Arch. Neurol. & Psychiat.* 50: 350 (Sept.) 1943.

pertinent to the problems of this study. Sixty-five of all of Dandy's patients with aneurysm both operated and not operated on had subarachnoid hemorrhage. Twenty of his patients died in the first attack of bleeding without operation. Twenty-two died in recurrent attacks of bleeding without operation. Twenty-three of the patients were operated on at variable times after their hemorrhage and the results were as follows:

Ten patients survived. There were 8 patients "well" at six and one-half, four, three and three-quarters, two and one-half, two, one and one-half years, six weeks and two weeks. One additional patient considered "well" had been operated on in 1942, and the report was published in 1944. Still another patient died of anemia one year after operation.

Thirteen of the patients died after operation, but inspection of their protocols reveals that the operative results are not as ominous as this implies. In 6 patients the aneurysm was exposed and clipped or thrombosed and the patient died within two days, except 1 whose aneurysm ruptured two months after operation at the site of cauterization. Four patients were mistakenly operated on for brain tumor, and the aneurysm was not revealed. The patients died shortly after craniotomy. Two patients were so ill at the time of operation that adequate procedures could not be performed. One patient died of pneumonia one month after ligation of the internal carotid. It is noteworthy that in the majority of these patients exploration was done without arteriographic evidence of the location of the aneurysm.

Although the operative procedure is hazardous, with the use of arteriograms to localize the aneurysm, the selection of patients who are good surgical risks and improvement in neurosurgical technique, reduction in mortality rate can be expected.

The situation can be epitomized as follows:

1. If the patient first comes under observation during the first or second week after a first attack of bleeding and has shown no evidence of continued bleeding, there is more than a 20 per cent chance that he will have a recurrence and die of subarachnoid hemorrhage. If arteriograms reveal a definite aneurysm whether localizing signs are present or not, the surgical risk of craniotomy is probably worth while.

2. If the patient first seeks medical attention more than a month after his initial hemorrhage and has significant symptoms referable to a probable aneurysm, arteriograms should be done. The decision concerning craniotomy will then depend on the location of the aneurysm and the nature of the symptoms.

3. If the patient first presents himself more than a month after his first hemorrhage, and he has had no recurrences and no localizing signs or symptoms, there is danger of rupture and death at some time in the future, but this danger is probably not as great as that attendant on craniotomy. In such instances arteriography is optional. If the patient in addition suffers from migraine, the cerebral vasodilatation²⁵ which often accompanies this phenomenon menaces the thin aneurysmal wall, and repeated and protracted insults of this kind may precipitate rupture of the aneurysm when the state of the wall makes this imminent. Therefore, in the long term management of patients with subarachnoid hemorrhage and migraine, if surgery is not feasible, every effort should be made to reduce the number of migraine headache attacks to a minimum.²⁶

25. Graham, J. R., and Wolff, H. G.: Mechanism of Migraine Headache and Action of Ergotamine Tartrate, *Arch. Neurol. & Psychiat.* 39: 557 (April) 1948.

The following method of management is therefore recommended:

A patient with a typical history and spinal fluid findings of subarachnoid hemorrhage, who is under the age of 60 and does not have evidence of severe generalized arteriosclerosis, subacute bacterial endocarditis or "bleeding tendency," is to be considered for surgery.

If the patient is alert and cooperative, does not have signs of continued bleeding and is observed during the first to the fourth week after the hemorrhage, arteriograms should be done. When an aneurysm can be visualized, craniotomy should be done if the aneurysm appears to be accessible to the surgeon. Localizing signs should indicate the side on which the arteriograms should be first done. Skull plates should be taken and searched for calcium shadows indicating the site of the lesion. When the arteriograms are negative, the patient should be confined to bed for from four to six weeks after the bleeding has stopped.²⁷

If the patient presents himself for the first time more than four weeks after the first hemorrhage and has persistent neurologic signs of an intracranial mass, arteriograms should be done and surgical operation considered. If the patient has survived without recurrence more than four weeks after the original hemorrhage and has no signs or symptoms, arteriograms and surgical intervention should be considered optional.

CONCLUSIONS

Twenty-nine per cent of patients who enter the hospital with subarachnoid hemorrhage die during the first episode of bleeding; 14 per cent die during recurrent bleeding between the second and the fourth week after the initial hemorrhage, and an additional 5 per cent die by the end of the first year. The majority of the remaining patients who survive the first year are alive three or four years after the initial hemorrhage. However, some die in from one to twenty-seven years of a recurrence of the subarachnoid hemorrhage; others die of some other illness. A few may live twenty-seven years or longer after the first attack without recurrences. Nevertheless, the threat of recurrent hemorrhages and death is always present.

On the basis of these findings it is recommended that patients who come under observation during the four weeks after a subarachnoid hemorrhage be subject to arteriography and subsequent craniotomy if an aneurysm is visualized.

Those who have had their last hemorrhage more than four weeks previously and who have localizing signs of an intracranial mass should have arteriography and subsequent craniotomy if suitable indications exist. When the localizing signs are absent in these patients, arteriography and appropriate surgical intervention are optional pending future development of neurosurgical procedures.

27. Lumbar puncture should be done only for diagnostic. Rarely it may be performed to lower dangerously increased intracranial pressure resulting in deepening coma, depressed respirations and rise in pulse and blood pressure. When lumbar puncture is done for diagnosis, only 1 or 2 cc. of fluid should be slowly withdrawn, and this should be centrifuged to demonstrate xanthochromia. On the rare occasions when it must be done for therapeutic purposes, a number 22 gauge needle should be used. The fluid is allowed to run up the manometer to establish the initial pressure level, and the manometer then tilted so that approximately the original pressure level is maintained. The fluid is allowed to run out of the top of the tilted manometer drop by drop, so that at the end of a half hour the pressure level is approximately half of the original pressure. Such a lumbar puncture is an emergency measure and should certainly not be done routinely at fixed intervals.

CONGENITAL ANOMALIES FOLLOWING
MATERNAL RUBELLA IN EARLY
WEEKS OF PREGNANCYWITH SPECIAL EMPHASIS ON CONGENITAL
CATARACTC. H. ALBAUGH, M.D.
LOS ANGELES

In 1942 Dr. N. McAlister Gregg¹ of Australia published the first report of congenital anomalies in infants born of mothers who had contracted exanthematous disease in the early weeks of pregnancy. Since then other reports have appeared in increasing number, both in Australia and in this country. In this communication the literature is reviewed and 9 additional cases are reported.

REVIEW OF LITERATURE

Although Gregg's report was carefully reviewed by Reese,² a brief summary of the important facts is included here. In Australia in 1940 there occurred a severe epidemic of rubella, which for the most part affected young persons who had not been exposed in previous epidemics. It is noteworthy that most of those women who were affected during pregnancy were primiparas. The description of the disease was pleomorphic and the diagnosis was often in question because there was a concurrent epidemic of sore throat which had apparently begun in the military establishments and had then spread to the civilian population. Gregg questioned whether, in some instances, the rash might not have been a toxic erythema accompanying the streptococcic infection of the throat.

Of the total of 78 cases reported by Gregg,¹ 13 were from his own practice, 7 he had seen personally with colleagues, and the remaining ones were reported to him by other colleagues.

Incidence of Rubella.—A history of rubella was obtained in all but 10 of the 78 cases. However, in that group of 10 the diagnosis was sufficiently suspected for them to be included.

Cataract.—All of the infants were found to have cataract at birth, bilaterally except in 16, in which there were unilateral lens changes. In all cases the nuclear portion of the lens was most affected, and in many the whole lens seemed to be involved. Absorption of lens material following needling was slower than in the ordinary congenital cataract. It was also noted that these babies were very sensitive to atropine in that they exhibited constitutional symptoms after only small amounts of the drug had been administered. Furthermore, in none of them was good pupillary dilatation obtained. Gregg urged early operation in order that development of the macula and of fixation might result from the stimulus of sight. He pointed out that this type of cataract fails to correspond to any previously described type of congenital cataract. He also made the observation that it is strange that rubella being as common a disease as it is, there have been no observations of congenital defects in infants ascribed to this cause.

General Observations.—In the series of 78 cases definite congenital heart lesions were reported in 44, and

in many others the diagnosis was uncertain. Patency of the ductus arteriosus was found in 3 cases at autopsy. Nearly all of the babies were underdeveloped and presented feeding problems.

The report of Gregg caused sufficient interest so that, under theegis of the National Health and Medical Research Council of Australia, Swan and his associates³ were commissioned to collect and correlate data on this syndrome. Their report in 1943, covering the period 1939 to 1942 inclusive, concerned itself with 61 infants examined, 36 of which were found to have congenital defects. Forty-nine of the mothers had rubella during pregnancy, and 31 of the offspring exhibited congenital defects.

Of the 31 mothers who subsequently gave birth to children with congenital defects, 29 had contracted rubella within the first three months of pregnancy. All of the 25 mothers who contracted rubella in the first two months had infants with congenital abnormalities, but of the 8 who contracted the disease in the third month of pregnancy only 4 gave birth to congenitally defective offspring.

Eye Defects.—Of the 14 children with eye defects, 13 had cataract and 1 had buphthalmos. All of the mothers had rubella in the first three months, and 12 of those 14 had rubella during the first two months. In 9 of the infants the eye defects were accompanied by heart lesions; 3 were mentally deficient; 1 had talipes equinovarus. Swan and his co-workers³ describe the eye changes as follows (p. 205):

The opacity then had the appearance of a flattened dense white disk in which six radiating lines were visible. These lines were presumed to be the two lens Y's superimposed, giving an appearance like a minute white starfish. If good mydriasis was obtained, a clear zone was visible peripheral to the opacity. The whole lens was very small, however, and at operation tended to move with the needle, so that the edge of the lens and suspensory ligament appeared within the pupillary margin.

Ear Defects.—Seven of the infants in the series with congenital defects were deaf-mutes, 2 of which also had heart lesions.

Cardiac Defects.—Of the 31 cases with congenital abnormalities, 17 had cardiac defects. Of these 8 had cataract, 1 had buphthalmos and 2 were deaf-mutes. Cyanosis was absent in all 17.

Other Defects.—Four of the babies were mentally retarded, 1 had hypospadias and one had talipes equinovarus. The impression was gained that persistent thymus was more common than in normal infants.

Swan and his associates were careful to verify the diagnosis and description of rubella and are reasonably certain that the diagnosis was correct and that this is not a new disease entity.

The most significant conclusion to be drawn from their report³ was that (p. 209):

On the available evidence, when a woman contracts rubella within the first two months of pregnancy it would appear that the chances of her giving birth to a congenitally defective child are in the region of 100 per cent, and if she contracts rubella in the third month they are about 50 per cent.

In 1945 Swan⁴ reported another series of cases. Of 70 offspring of women having rubella during pregnancy, 49 exhibited congenital abnormalities. Twenty of these babies had eye defects. Cataracts were present in 17, of which over half were afflicted with heart dis-

Paper in a symposium on Congenital Disorders Involving the Skin, published under the auspices of the Section on Dermatology and Syphilology.

2. Reese, A. B.: Congenital Cataracts Following German Measles in the Mother, *Am. J. Ophth.* 27: 483-487 (May) 1944.

3. Swan, C.; Tostevin, A. L.; Moore, B.; Mayo, H., and Black, G. H. B.: Congenital Defects in Infants Following Infectious Diseases During Pregnancy, *M. J. Australia* 2: 201-220 (Sept. 11) 1943.

4. Swan, C., in discussion on Congenital Cataract in Children Following Maternal Rubella, *M. J. Australia* 1: 122 (Feb. 3) 1945.

ease, 1 with buphthalmos, 1 with bilateral central visual defect and 1 with squint; 3 were mentally deficient, and 1 had talipes equinovarus.

Of the 45 with congenital defects, 15 were deaf-mutes, 5 of which had heart disease also. Swan found that heart disease occurred more often in association with cataract than with deaf mutism.

Cardiac abnormalities were present in 26 cases of the series. Seven had heart disease with no other apparent defect, 10 had cataract, 5 deaf-mutism, 1 buphthalmos, 2 mongolism and 1 squint. Swan cited Dr. Mervyn Evans, who had found congenital dental abnormality consisting of retardation of eruption in 23 out of 34 babies whose mothers had rubella during early pregnancy. As Gregg had thrown some doubt on the diagnosis of rubella, Swan and his co-workers were careful in their study of the symptomatology of the reported cases. They were led to the conclusion

1 case morbilli. In the 2 cases in which the exanthem occurred during the second month of pregnancy the infant developed cataract, whereas in those in which the disturbance occurred during the third month congenital glaucoma appeared.

In October 1944 Erickson⁶ reported 11 cases of congenital malformation of the eyes and heart following rubella in the mother in early pregnancy. One of the cases revealed that rubella had been contracted at two and one-half months, the latest of any of them, and in this case cataracts were not present but there were opacification of the cornea and microphthalmia.

In February 1945 two reports were published. Perera⁷ reported 1 case of congenital cataracts following rubella in the mother during the second month of pregnancy. Greenthal⁸ reported 2 cases in which the mother had had a medical diagnosis of rubella during the first two months of pregnancy. One of the babies

Cases 2, 3 and 6 are reported from the Ophthalmological Service of the Children's Hospital, Los Angeles.
Case 5 is reported by courtesy of Dr. Alfred Robbins of Los Angeles.
Case 1 is reported by courtesy of Dr. John P. Lordan of Los Angeles.
Cases 7 and 8 are reported by courtesy of Dr. Robert A. Norene of Los Angeles.
Cases 4 and 9 are from the author's private practice.

that analysis failed to support any other diagnosis than that of rubella. They also noted that in 35 of the 49 mothers who were diagnosed as having rubella the diagnosis was made by medical practitioners of wide experience.

The first report to appear in the American literature was that of A. B. Reese² in May 1944. He reviewed thoroughly the then extant material from Australia and reported another 3 cases of his own. All 3 of the infants he saw were afflicted with congenital cataracts and congenital heart lesions, and all of the mothers had contracted rubella within the first trimester of pregnancy. Reese emphasized the characteristic of shallow chamber; it made him cautious about dilating the pupils for fear of precipitating glaucoma. Again, he raised the important question that if the so-called rubella was true rubella then why had not the relationship between its occurrence and congenital anomalies been recognized before?

A few months later Rones⁵ reported 4 more cases. In 3 of his cases the mother had had rubella and in

suffered deaf-mutism with no other apparent lesion, and the other had a unilateral cataract and a heart lesion as well as mental and physical retardation.

This relationship between maternal rubella and congenital defects in the offspring first entered the national consciousness early in 1945 with the remarks of Dr. P. M. Stimson⁹ of New York, whose discussion of the subject at the New York Academy of Medicine was reviewed (without Dr. Stimson's knowledge) by a *Time* magazine reporter.

REPORT OF CASES

Nine cases of congenital abnormality in the infant following an exanthem in the mother in the early weeks of pregnancy are herewith reported. For the sake of brevity and ready reference these cases are reported in table form. It is suggested that the term rubella be

used in place of German measles because the public has felt that German measles is a relatively innocuous disease.

COMMENT

Swan¹⁰ has noted that grossly the lens in this condition has the appearance of being smaller than normal, with the densest opacity in the nucleus. He was fortunate enough to examine sections of the lens from autopsy material and discovered that the characteristic picture is that of complete necrosis of the nucleus with more or less distortion of the secondary fibers, depending on the time of the disturbance. He considers that disturbance of secondary fibers indicates that the process, whatever it may be, continues to be evident after the seventh and eighth weeks, since those fibers are not formed until after that time.

All the cardiac defects were related to the septums and the ductus arteriosus. Various degrees of severity of such defects have been observed, from simple patency of the foramen ovale or patency of the ductus arteriosus to large openings between both auricles and ventricles, with patency of the ductus arteriosus. It is known that the critical period for the development of cardiac defects is from the fifth to the eighth week.

As yet no examinations of the internal ear have been reported.

Stages in the development of the human lens are approximately as follows:¹¹

Four mm. stage (third week), lens plate develops.

Five mm. stage, lens pit present.

Seven mm. stage, lens vesicle present but still connected to surface by lens stalk.

Nine mm. stage, lens vesicle separates from surface.

Sixteen mm. stage (sixth week), lens cavity obliterated.

The foregoing data would indicate that the critical period for attack on the lens nucleus would be before the eighth week of pregnancy. This assumption is certainly consistent with the reported statistics on disorder of the lens. Although at the present stage of knowledge any hypothesis would be purely speculative, it would seem likely that either one or both of two processes is responsible for the lenticular lesions. For instance, it is well known that embryonic and undifferentiated tissues are most susceptible to virus invasion. This fact is made use of in the laboratory in that viruses are cultivated on the embryo of the chick. In the human lens, differentiation begins to take place during the eighth week and thereafter progresses rapidly and very likely with reduced vulnerability to virus invasion. The same logic may be applied to susceptibility of the placental barrier. The status of vulnerability to virus infection is about the same for all the other vital organs of the body.

On first consideration it might seem logical to assume that, since the virus of rubella appears to attack the ectodermal structures in the adult, it might do likewise in the embryo. It would be easy, thus, to account for lesions in the lens, as it is an ectodermal structure and at the time of the disease may still have a connection with the surface ectoderm. Such an assumption could not be held so logically when the cardiac lesions

are considered. E. W. Hurst¹² is of the opinion that the lesions are due to faulty nutrition as a result of disturbance in the vascular supply consequent on invasion by the virus or its products.

Several questions have arisen out of the appearance of this new disease association. Some of them might be listed as follows:

Is the disease which affects the mother rubella? Is it rubella in a new form or of increased virulence? Why has this association not been recognized before? Ida Mann¹³ expressed the opinion that the defects were not a new complication of rubella but a previously undetected result of it and possibly of other infections.

Another question that might well be posed, in addition to all the others, is Why do not all the anomalies occur more uniformly in each individual infant? For instance, why should unilateral cataract occur in some children? Why does one have cataracts with heart disease when another has cataracts without any other anomaly? If the disease process continues over a considerable period of time, as Swan suggested, then the timing of the disease should not have such a critical part in the locus of the anomaly.

Rones,⁵ cautious in his opinion, notes that his findings tend to bear out the assertion of Swan that all mothers with exanthematous diseases such as rubella in the first two months of pregnancy will give birth to children with congenital abnormalities. He should be agreed with when he iterates that many thousand cases will be needed for compilation before these findings are accounted as fact rather than as coincidence. He has recommended that a thorough statistical study be carried out by some national agency to establish the validity of present assumptions.

The fact that buphthalmos has been reported as a congenital defect following maternal rubella in the early weeks of pregnancy would tend to bear out the theory of interference with blood supply in the structures at the angle of the anterior chamber. The report of Rones⁵ would indicate that buphthalmos occurs when the exanthem is contracted during the third month. Any necrosis with consequent fibroplastic process would certainly interfere with the later gradual atrophy of material at the anterior chamber angle. Apparently the atrophy mentioned is responsible for the development of the filtration area at the angle. If scar tissue were present, such atrophy could not take place.

In answer to the inquiry why other diseases in early pregnancy are not responsible for the development of similar anomalies in the infant, Swan¹⁰ has postulated that the severe virus infections such as morbilli may kill the fetus and lead to spontaneous abortion, whereas the milder diseases such as rubella cause only damage to the fetus.

Whatever the pathogeny of these congenital abnormalities, it is certain that the suggestions of the Australians that rubella and its causative agent be more carefully studied are to be taken seriously both here and abroad.

In the management of these cases, Gregg¹ stressed the desirability of early operation in order to avoid

the development of nystagmus. In monocular cases operation might well be postponed until the infant is a year old or more, as binocular vision is rarely developed in unilateral aphakia. However, in all cases the time of operation is subject to the general health; many of the infants are feeding problems with poor general health, and many of them have cardiac lesions which make the administration of a general anesthetic risky. Furthermore, at least from the medicolegal aspect, the desirability of x-ray treatment to the thymus before surgery should be considered seriously.

Gregg,¹ and Swan² too, performed needlings in the cataract cases in which they operated. It was found that dissection was difficult because of the small cornea and shallow chamber. It was their opinion that simple needling was ineffective and that break-up of the whole cataract was necessary. In some of the cases reported herewith the same difficulties were experienced. However, Dr. Alfred Robbins¹¹ of Los Angeles used his suction method in 1 of the cases. Recovery was rapid and uneventful and the fundus could be observed immediately after surgery. In this 1 case Dr. Robbins did not feel that the fundus differed materially in appearance from that of a child with the ordinary type of congenital cataract. This is the first reported observation of the fundus in a case with this type of a cataract.

Nearly all of the reports have indicated that dilation of the pupil with atropine was both unsatisfactory and hazardous. As a matter of fact, such is the case in almost any newborn baby because the fibers of the dilator muscle are not completely developed at birth. The fact that constitutional symptoms appeared is not remarkable, because these were underdeveloped babies who might be expected to be less tolerant to ordinary doses. Furthermore the average drop from an ordinary ophthalmic dropper contains approximately $\frac{1}{150}$ grain (0.4 mg.) of atropine when a $\frac{1}{8}$ per cent solution of atropine sulfate is used. Several drops are usually used to dilate the pupils prior to surgery, and it can be seen easily that an unusually large amount of atropine may be absorbed by the infant. Little wonder then that constitutional signs are frequently seen. In the series of cases reported here much more satisfactory results, both as to dilatation of the pupil and absence of constitutional signs, were obtained with 2 per cent neosynephrin. No untoward effects were noted even in those with cardiac lesions.

As yet no report has appeared which attempted to evaluate accurately the visual results of surgery. However, in cases 4, 5 and 7 reported here, in which survival occurred and operation was performed, there is sufficient vision so that these infants are able to orient themselves and to move about by themselves.

As the occurrence of rubella in early pregnancy apparently leads to such crippling consequences in the offspring, it becomes a problem of no little importance from the public health standpoint.

Swan and his associates² suggested two methods of attack: the taking of steps to isolate the causative agent with a view to preparing a protective vaccine, and the use of convalescent serum, which should be studied both for use in the incubation period and as a prophylactic for nonimmune pregnant women. They also

observed that termination of pregnancy had been suggested, but they felt that no legal grounds exist in Australia, at least, and that legislation to such an end might be open to abuse. Erickson⁶ suggested that girls should be exposed deliberately to rubella before maturity and that, particularly during epidemics, women who are in early pregnancy and have not had rubella should be given convalescent serum. Greenthal⁸ is of the opinion that every child should be allowed to contract rubella before maturity in spite of the danger of complications. Both Reese² and Stimson⁹ mentioned the problem of whether women proved to have rubella in early pregnancy should be aborted.

Obviously there is no argument concerning the desirability of making studies on the nature of the causative agent of rubella with a view to the development of a protective vaccine. However, there is room for discussion on the use of convalescent serum. It is evident that in many instances women do not realize that they are pregnant until after the first month and sometimes until much later, so that the prophylactic use of convalescent serum would not always be practicable. Furthermore, except in the large cities where there are communicable disease hospitals or such units in general hospitals, convalescent serum might not be obtained easily.

It is not difficult to agree with Erickson⁶ that all girls should be exposed to rubella before maturity if such exposure can be carried out practically. However, it should be kept in mind that such exposure is not without danger, for complications do occur. Christian¹⁵ mentions encephalitis and purpura and in rare instances albuminuria, arthritis, nephritis, pneumonia and colitis. Owen and Greenaway¹⁶ reported meningo-encephalitis as a complication.

Consideration of abortion of women who have contracted rubella in early pregnancy cannot be lightly entertained. In the first place, legal precedent would have to be established; in most states abortion is now justified only in order to save the life of the mother. Furthermore, as Swan pointed out, specific legislation, if it could ever be passed, might well be open to abuse, particularly because the diagnosis of rubella is not always certain. Too there are deep-rooted religious scruples which present an almost insurmountable barrier to such a procedure.

The attitude of the general public with widespread knowledge of this disease association is worthy of consideration. Dr. Philip M. Stimson¹⁷ of New York is the man most able to report on such an attitude. He wrote "A doctor who was present at my lecture [before the New York Academy of Medicine] told the magazine *Time* what I had said about rubella; hence the account that appeared in the March 5 number and which I did not see until after it was published. As a result of this not altogether desirable publicity I have had a number of letters from all over the country, most of them telling of additional instances of abnormal babies following rubella in the first two months of pregnancy. In 1 case the mother wrote that now she

understood why her baby had been afflicted with congenital cataracts and congenital heart disease and general underdevelopment, and she felt she could go on and have more children—something she had not thought she could do, fearing that there was a family taint somewhere. Only one letter—this from a lawyer in Tucson, Ariz.—protested against the statement that abortion would have to be considered very seriously; and a rather remarkable fact is that I have received no letters from anybody saying that they had rubella early in pregnancy and had had a normal baby. In fact, I have yet to hear of an authentic such case."

SUMMARY

Available data would suggest that 100 per cent of the mothers who contract rubella in the first two months, and approximately 50 per cent of those who contract it during the third month, will give birth to infants with congenital anomalies.

The commonest lesions in the infants are cataracts, cardiac septal defects and patent ductus arteriosus, deaf-mutism and microcephaly.

Nearly all of the infants are poorly developed and are feeding problems.

ABSTRACT OF DISCUSSION

DR. F. W. LYNCH, St. Paul: Dr. Albaugh deserves thanks for calling attention to the now clearly established fact that when rubella occurs during pregnancy it frequently results in one or more congenital anomalies. The prognosis is more severe when the disease occurs as early as the second month. It seems likely that when the disease occurs later the fetus may not be so gravely influenced. Some years ago I reviewed the influence of infectious disease on the fetus (*Arch. Dermat. & Syph.* 26:997 [Dec.] 1932) and found that in the more serious disorder rubeola the fetus rarely survived and in 47 cases of fetal smallpox there was a mortality rate of 80 per cent. Congenital abnormality other than the eruption of its scars had not then been recorded. In 9 supposed examples of fetal vaccinal eruptions only 2 infants lived and their disease was acquired in the ninth month of pregnancy. This review also concluded that vaccination in pregnancy, even when early, seldom transmitted immunity to the fetus. Such observations and the evidence cited by Albaugh support a belief that these congenital abnormalities of the eye, heart or nervous system are the effect of disturbance in the vascular supply rather than the direct influence of the virus. This report should spur attempts to develop a protective vaccine or make more generally available the benefits of convalescent serum therapy for rubella. Regarding justification for deliberate previous exposure, the situation is probably comparable and the risks of complication are probably no greater than with vaccination in the case of smallpox. In consideration of "prophylactic" abortion when rubella occurs in early pregnancy there are legal and religious questions and the added moral one of uncertainty as to the natural outcome. It is as yet too soon to accept the statements of some authors that all the children will have congenital abnormalities. In the case of smallpox occurring (later) in pregnancy it was noted that in twin births one fetus might be apparently free from influence while the other had severe disease. Regarding the difficulty of the statistical approach, it was recently noted in the *Lancet* (2:20 [July 7] 1945) that all studies have started from known cases of malformation and that the reverse is not practical because in a mild illness such as rubella many cases will remain unreported or even unrecognized. A paper such as Dr. Albaugh's serves the public health purpose of notifying doctors of the probable outcome of rubella in pregnancy and the need for pregnant women to avoid contact with the disease.

CONGENITAL CATARACTS IN SISTERS WITH CONGENITAL ECTODERMAL DYSPLASIA

H. N. COLE, M.D.

HORACE K. GIFFEN, M.D.
CLEVELAND

J. T. SIMMONS, M.D.
ERIE, PA.

AND

GEORGE M. STROUD III, M.D.
CLEVELAND

An American dentist, Guilford,¹ first reported a case of congenital ectodermal dysplasia of the anhidrotic type. The man, aged 48, was edentulous and had almost complete absence of taste and complete anosmia. He was hypotrichotic and never perspired. At almost the same time Atkinson² presented before the Philadelphia Medical Society a man aged 40 who had never had teeth or any distinct growth of hair on the scalp except the downy hairs which are seen in early infancy. He was also destitute of the sense of smell and almost of that of taste. His skin appeared to be unprovided with sweat glands, as he never perspired, and when working actively he was obliged to wet his clothes in order to moderate the body heat. He could sleep in these wet clothes in a damp cellar without catching cold. His jaws presented the appearance seen in persons who have lost all their teeth. Hair was present in the axillary and pubic regions, but the downy hair which is usually seen over the skin at large was wanting, except on the scalp. His maternal grandmother and uncle were similarly defective, and the patient was among the younger of twenty-one children. He was a man of very good health, having never been seriously ill, and, although not able to chew his food in the ordinary manner, had never suffered from dyspepsia. The secretion of urine was unusually abundant. He was married and had eight children, among whom were two girls, both of whom lacked a number of teeth.

Since then many more of these cases have been reported, and in 1920 Goeckerman³ reported the first female with the anhidrotic type of congenital ectodermal dysplasia—congenital absence of teeth and sweat glands, hypotrichosis and almost complete absence of sebaceous glands. Furthermore, there is another group of cases with a variety of gradations of the aforementioned symptom complex. These patients may have various parts of the developmental ectoderm involved. Perhaps in one group an almost complete hypotrichosis⁴ will be the main picture; again, the nails may be absent, hypoplastic or grossly deformed. The patient of MacKee and Andrews had satyr ears in addition to the ectodermal dysplasia. Syndactyly⁵ and polydactyly have occurred. There may even be an aplasia or hypoplasia of the pharynx, anomalies of the knee joints and defects of the

clavicles.⁹ In the cases reported by Cole, Driver, Giffen, Norris and Stroud⁷ and by Hailey⁸ there was even the congenital absence of a digit together with striking, systematized, pigmented and vascular changes on the skin of the extremities and other cutaneous changes atrophic in character. Moreover, Cockayne⁹ in his treatise on "Inherited Abnormalities of the Skin and Its Appendages" says that Deutsch reported a case with a cleft hand.

As the title of this paper indicates, ectodermal elements in development are the ones affected, and it might be expected that among other organs the eye might also be involved.

FIG. 1.—Anterior view of the infants, showing the dark reddish pigmented process surrounding apparently atrophic white areas with absence of hair. As children became older, the trunk also was involved.

CASE HISTORIES¹⁰

In this paper are presented two sisters having a picture approaching closely the anhidrotic type of congenital ectodermal dysplasia, but perhaps best classified as a combined ectodermal dysplasia, and also having congenital cataracts.

CASE 1.—History.—M. A., a white girl aged 2 years, first seen in February 1941, had a skin eruption which was first noted when she was very young.

The father, aged 28, is living and well. His incisors are slightly conical and are more widely spaced than usual. The mother, aged 26, is well. There is no known insanity, tuberculosis, congenital heart disease or epilepsy in either side of the family. The paternal great-grandfather and great-grandmother on the grandfather's side were normal and had six boys and four girls, who had normal skin, eyes, hair and teeth.

The maternal great-grandfather and great-grandmother on the grandmother's side were normal and had five boys and four girls. All had normal hair, skin, eyes and teeth.

The paternal grandfather and grandmother had one boy, one girl and a girl from a previous marriage, all of whom were normal. The grandfather is living and well; the grandmother died of influenza in 1918 (The boy is the father of the defective children.) No history of this condition in any of the children of the aunts or uncles is known except that a daughter of one of the father's uncles has a congenital myasthenia with muscle imbalance.

The maternal grandparents are normal and living and well, they have no recollection of any similar condition in any of their relatives. They have five boys with progeny of five boys and two girls, all living, well, and normal; they have four girls—three of the girls having between them one boy and one girl, living and well. The fourth girl is the mother of the defective children.

There are no intermarital connections this far back. No one knows of a similar condition in either family for the three generations of aunts, uncles, cousins, great aunts and great uncles. There is no history of eczema in the family tree.

The parents of the defective children have had two more girls since the birth of the defective children, one is now 6 months and the other 2½ years of age. Thus far both have normal hair, skin and eyes. Teeth are normal in the older child and are unerupted in the younger baby.

The only other case of congenital abnormality in the family is that in the sister of this patient (case 2).

The general health of this child has been fairly good. She weighed 5 pounds (2,268 Gm.) at birth, and her mental development has been greatly retarded. She talks practically none at all. She had pneumonia at the age of 1 year. She did not walk until she was 22 months of age. The teeth erupted at the usual time. She does not see and has a squint. A cataract was seen in the right eye at the age of 3 months and in the left at 6 months.

Present Illness.—When this child was very young, the mother noted that the skin over the legs was dry and red. The condition progressed to other parts of the body and grew worse. No body sweating has been noted, and in hot weather the child is very fretful.

Physical Examination.—This child (the larger one in figs. 1 and 2) is moderately small for her age. She is not expressive and says but one or two words. Skeletal abnormalities are slight, but there is some accentuation of the frontal bosses and the supraorbital ridges, with relative depression of the bridge of the nose. There is moderate exophthalmos and an internal strabismus. The inner epicanthic folds are thickened and webbed over the medial part of both eyes. There are bilateral cataracts. The nasal mucosa is pale and shagbilly crusted. There are fourteen widely spaced, small teeth, which are hypoplastic and conical, and the enamel is pitted in places. The deciduous teeth are hypoplastic. There is a hypoplasia of the nail.

The most striking abnormalities are found on the skin. On casual observation the skin changes appear as extensive patches of cutis marmorata. On close inspection the skin of most of the body is mottled with dull, red, confluent, sharply demarcated and mildly elevated areas which fluctuate very slightly with pressure. Between the darker areas are small pale patches 3 to 10 mm. in diameter of 3 mm. in diameter. The skin changes are most pronounced over the extremities and the face. No hair is visible over the body, but the scalp has a small long, fine, hair on the head.

10. Cockayne, H. A.: *Inherited Abnormalities of the Skin and Its Appendages*. London, Oxford University Press, 1935.
11. These cases were seen and studied during the course of a study of Dr. Norman D. Gilbert's case of Ectodermal Dysplasia.

Laboratory Examination.—The urine findings and the blood picture are essentially normal. The Kline diagnostic blood reaction is negative. Blood chemistry studies show sugar 53 mg., calcium 11.3 mg., phosphorus 4.4 mg. and cholesterol 196 mg. per hundred cubic centimeters of blood, and the phosphatase 0.39 unit per hundred cubic centimeters. Further opportunity to study the blood sugar was not offered, since the child was taken home.

Roentgenography reveals undeveloped, unerupted molar teeth in the jaws. No abnormalities are discovered in the bones of the extremities, trunk or calvarium.

Biopsies were taken from the anterior thigh and the abdomen. The findings of this study will be given later, after description of other findings in case 2.

Hospital Course.—The child remained in the hospital for only three days, but during this time the temperature varied from 37.0 to 37.6 C. (98.6 to 99.7 F.). Since she was removed on short notice, no opportunity was presented to make any temperature studies of her body under varying conditions.

CASE 2.—History.—C. A., a white girl aged 10 months, seen in February 1941, at birth also weighed 5 pounds. The delivery was spontaneous and without complication. She has been "cross eyed" since early infancy. Her skin is similar to that of her sister. This change was noted early in life. No mental deficiency was detected at first, but later her mentality was found to be very poor. She developed cataracts in both eyes at about 2 years of age.

Physical Examination.—This infant (the smaller child in figs. 1 and 2) is normally developed and nourished for her age. She has no teeth. The palatal arch is high, but otherwise she shows no abnormalities of the bony framework of the body. The changes about the epicanthic folds and nasal mucosae are similar to those described for her older sister. The nails are rudimentary. The skin changes are similar to those of the older child, but this baby shows a few crusted areas (ecthymas) over the buttocks and legs, with some scaling about the knees.

Laboratory Examination.—The urine and the hemograms are essentially normal. The Kline diagnostic blood reaction is negative. Blood chemistry reveals blood urea nitrogen 19.5 mg., sugar 97 mg., calcium 11.1 mg., phosphorus 5.0 mg., and cholesterol 144 mg. per hundred cubic centimeters. The glucose and adrenal tolerance tests are within normal limits. Roentgenographic studies reveal no osseous or dental abnormalities. Biopsy specimens were removed from the anterior thigh and from the back.

Hospital Course.—When placed within three blankets for about three hours, the child became fretful, lacrimated slightly and showed moderate sweating over the scalp and slight perspiration over the rest of the body. The temperature rose less than 1 degree centigrade. During three weeks in the hospital the temperature varied from 36.0 to 38.2 C. (96.8 to 100.7 F.).

MICROSCOPIC STUDIES¹¹ IN BOTH CASES

Biopsies were taken of skin from the anterior thigh and the abdomen in case 1 and from the anterior thigh and the back in case 2. Serial sections were cut of each specimen. From each of these sites sections were stained for elastic tissue, connective tissue, iron and melanin. The remaining sections from each site were stained with hematoxylin and eosin. In all there were 38 sections from the abdomen and 81 sections from the anterior thigh in the first case. In the second case there were 52 sections from the back and 54 sections from the anterior thigh. Pigment of the stratum germinativum was scanty and often absent. The pigment found in the upper corium and midcorium did not contain iron in any of these sites but showed the reactions for melanin.

CASE 1.—Anterior Thigh.—The epidermis varied considerably in thickness and had a rather thick keratin layer and shallow, sparse rete pegs. The corium was irregular in thickness. It

was in part dense, with abundant collagenous and elastic tissue, but in other regions the subcutaneous fat extended high into the corium. No hair follicles and no sebaceous glands were present in any of the sections. Poorly developed sudoriferous glands were present, but in most places even these were reduced in number or absent. There were occasional oblique, small bundles of smooth muscle in the position and with the shape of the arrector muscles. None of these were well developed. In the upper corium were variable numbers of pleomorphic, usually elongated cells packed with dark, yellowish brown melanin pigment. Most of these pigment cells were close to blood vessels, which appeared in moderate numbers.

Abdomen.—The epidermis varied from 4 to 8 layers in thickness and had a moderately thick keratin layer and irregularly developed rete pegs. Pigment in the basal layers was scanty. The corium was largely dense and thick, but it too contained

Fig. 2.—Posterior view, children aged 5 and 6, showing the widespread cutaneous change and absence of hair. Note its extensive character over trunk.

some zones of adipose tissue extending from the subcutis high up into the corium. Sweat glands were poorly and irregularly developed. Occasionally there were rudimentary hair follicles and sebaceous glands, but neither of these were fully developed. Foci of melanin pigment were prominent in the upper corium.

CASE 2.—Anterior Thigh.—The epidermis was irregularly thickened and had a moderately thick keratin layer, poorly defined, shallow, rete pegs and little or no pigment in the basal cell zone. In this case too the corium was focally replaced by fat extending from the subcutaneous tissue high up into the corium, while between these areas there were strands of collagenous and elastic tissue. Occasional arrector muscles were found in the upper corium, but there were no hair follicles in any of the sections. The imperfect arrector muscles were without attachment. Moderate numbers of normal sudoriferous glands were present in places deficient in number or absent. Pigment cells were noted in the upper corium.

Back.—Biopsies of the back showed epidermis that varied from normal to slightly increased thickness. There were well

11. Dr. Howard Karsner, professor of pathology and director of the Institute of Pathology, and Dr. Harry Goldblatt, professor of experimental pathology and associate director of the Institute of Pathology, concurred in the microscopic findings and the conclusions drawn from them.

defined rete pegs and moderately cellular papillae of the upper corium, with most of the corium thick and dense. There were moderate numbers of imperfectly formed hair follicles, a few poorly developed sebaceous glands and histologically normal sudoriferous glands. The collagenous connective tissue and the elastic tissue were abundant. Scattered lymphocytes were present around the vasa of the upper corium.

CASE SUMMARIES

With a normal mother and a father with only minor dental defects, two sisters are mentally subnormal and the older one shows evidence of dental hypoplasia. The teeth are present in the other child but as yet are unerupted. Both have atrophic nasal mucosae. Both children stand heat poorly, and the second child experimentally shows a subnormal response to heat with little perspiration. In both children there is almost complete

plasia, and especially for bilateral congenital cataracts and extreme internal strabismus. The term dysplasia is preferred rather than defect. "Dysplasia" is defined as "an abnormality in development." The other ectodermal elements seem to be more frequently involved in this rare malady. And yet, as far back as 1875, Sir Jonathan Hutchinson¹² stated that surgeons were aware of a relationship between congenital cataracts and badly developed teeth. He stated that the cataract was of the lamellar or zonular type, neither the nucleus nor the periphery of the lens being involved. He incorrectly interpreted the condition of the teeth to be secondary to the use of "fit" powders containing mercury, for he had noted the frequency of "fits" in these cases. The 2 patients studied have had no convulsions.

In 1879 Tilbury Fox¹³ described a patient suffering from epidermolysis bullosa hereditaria. This patient had in addition an atrophy of the skin of the forehead, a hypoplasia of the permanent teeth, "weak eyes" and absence of the nails.

Nettleship¹⁴ also has studied lamellar cataracts, fits and hypoplasia of the enamel of the teeth. The fits occur between the ages of 6 and 18 months. Milk teeth are normal, but permanent teeth with the exception of bicuspids lose their enamel and are pitted. Only the crowns of the molars may be affected. He stated that dental changes are present only where large cataracts are found. Consanguinity appears to be rare, except in the group of complete congenital cataracts. He too has fallen into the error of ascribing the tooth condition to mercury given for the convulsions.

Eshner¹⁵ in 1905 reviewed all cases of congenital alopecia up to that date and reported the case of a man aged 64 with an atrichia, a hypoplasia of the nails, perspiring infrequently and having a retinitis alleneas.

Hyde in 1909 discussed the subject of congenital alopecia and described a girl aged 3 with a hypoplasia of the hair and nails, a syndactyly and eyes showing opaque patches on the retinas. He also mentions Nicolle and Halpié's¹⁶ report on congenital alopecia in six generations affecting 36 individuals. These patients often had changes of the teeth and nails and impaired sense of taste and smell. Defective perspiration was observed, and "anomalies of the eyes are apparently among the rarest of the phenomena associated with natal and postnatal hair defect."

Schäfer's¹⁷ male patient with an acne-like follicular keratosis on circumscribed areas of the skin also had leukokeratosis of the mucous membrane, sealike areas of the scalp, double cataracts (congenital) and changes on the laryngeal mucous membrane.

Schäfer¹⁸ saw a patient with defective vision and divergent strabismus, absence of the left upper incisors, in one of two sisters with a complete anhidrosis. Being a dentist, he mentioned nothing more specific as to the eye trouble.

absence of hair. Both have bilateral congenital cataracts and internal strabismus and were seen by one of the authors (J. T. S.) with regard to them. He reports that they have congenital cataracts which "explode" on rupturing the capsule. Thus far he has operated on three of the four eyes successfully. The squint is the internal, extreme degree type, the right eye being the crossed eye in both children. Ophthalmoscopic view of the retinas and nerve heads appears normal.

Microscopic study of serial sections from two biopsies in each child shows irregular hypoplasia of the skin and accessory structures, sweat glands, sebaceous glands and hairs. In places all three are completely absent, in others rudimentary or present in part, at least sebaceous and coil glands.

COMMENT

The cases described are notable for congenital ectodermal dysplasia approaching the anhidrotic type but probably better classified as a combined ectodermal dys-

Maggs's¹⁹ patient, aged 18, had a hypodontism, microdontism, bilateral microphthalmia and almost complete aniridia.

Christ²⁰ has reviewed the entire subject of congenital ectodermal dysplasias in relation to eye involvement, and the interested reader should refer to this review. He quotes Werner,²¹ who has noted the syndrome of cataract formation (congenital), certain malformations of the fingers, atrophies of the skin and fine curly hair.

Werner quotes Hofstein "that people with anomalies of the hair and certain types of cataract often have a deficient enamelization of the teeth." Our 2 cases are the only ones we have been able to find in the literature in which all the ectodermal elements, teeth, hair, nails, skin, including the sweat and sebaceous glands, the nervous system and the eyes are involved.

Enough has thus far been said to indicate that this remarkable and very rare congenital condition involving these two sisters is inherited. The typical case of major congenital ectodermal dysplasia of the anhidrotic type is considered to be a sex linked recessive (transmitted by the apparently normal female and affecting some of the males). However, there have been reported typical female cases which must be forms of the disease of other causation and which Cockayne would classify as incomplete dominant (abnormality transmitted by direct descent from the affected members of a family to some of their children, who in turn transmit it, and so on. But the normal children do not transmit it, and it does not reappear in their descendants). Nettleship considered his cases of congenital cataracts with hypoplasia of the enamel as an example of simple dominant inheritance—the sexes were equally affected. The type of heredity in these cases is considered to be of an incomplete dominant form.²²

SUMMARY

Two sisters, aged 10 and 22 months respectively, had congenital cataracts of the lamellar type, extreme internal strabismus, hypoplasia of the nails, almost complete alopecia, atrophic nasal mucosae and a generalized hypoplasia of the skin. Both children stand heat poorly, both children are subnormal mentally and the older has a dental hypoplasia. Microscopically there is an irregular hypoplasia of the skin and accessory structures, sweat and sebaceous glands and hair. In places all three are completely absent.

Involvement of all ectodermal elements as seen in these sisters is very rare if not unique, and the picture presented approaches closely to that of congenital ectodermal dysplasia of the anhidrotic type but perhaps would better be classified as a combined ectodermal dysplasia.

The dysplasia of ectodermal elements seen in these sisters with only a suggestive dental abnormality in the father and no other family history is probably "incomplete dominant" in type.

ABSTRACT OF DISCUSSION

DR. EDWARD A. OLIVER, Chicago: Cockayne, in his textbook on inherited abnormalities of the skin and its appendages, gives as the outstanding symptoms of anhidrotic ectodermal dysplasia small size and delicacy of constitution, a total absence or deficient number of teeth, conical incisors and bicuspid, and molars with sharp, hooked cusps, short, fine, pale and scanty hair, chronic rhinitis with subsequent loss of the sense of smell, absence of sweating and sometimes, if not always, absence of the lacrimal glands. This report of Dr. Cole and his co-authors is most unusual in that these children, in addition to showing practically all of these symptoms, also show hypoplasia of the nails, a generalized hypoplasia of the skin and, what is still more rare, congenital cataracts. The authors have covered the literature well. Congenital ectodermal defects of a partial character, such as congenital aplasia of the teeth, hypotrichosis and even congenital absence of circumscribed patches of the skin, are no longer rarities. A number of such cases have been reported. These authors' cases are unique in that there is involvement of all ectodermal elements. One of the most interesting features of the majority of these cases is the almost complete absence of sweat glands. By careful microscopic examination the reporters have demonstrated that in these little girls there is an irregular hypoplasia of the sweat and sebaceous structures and in places that all three are completely absent. In practically all of the reported cases of ectodermal defect inability to perspire in warm weather is a prominent symptom, and, while these patients are entirely comfortable in the winter months, they suffer intensely in hot weather. In view of the fact that there was no history of abnormalities on either side of the family, with the exception of a suggestive dental abnormality in the father, the authors are correct in classifying these cases as "incomplete dominant" in type.

DR. GEORGE M. MACKEE, New York: Cole and his collaborators are correct in stating that their patients present an exceedingly rare or even unique variety of combined congenital ectodermal dysplasia, because in these 2 patients all ectodermal elements were involved. Occasionally, I encounter minor ectodermal defects and rarely a major case, but I have never seen a patient such as these two sisters. The case reported by Andrews and me was one of major ectodermal dysplasia, but some of the ectodermal elements were normal. In all the congenital ectodermal defects that I have seen, the eyes were either normal or such abnormalities were overlooked. Congenital cataracts or idiopathic cataracts in children, adolescents and young adults, in the absence of other congenital defects, are not uncommon and have been mistaken for x-ray or radium injuries. There are a number of records of congenital cataract occurring in neurodermatitis disseminata, in which also there was mild ichthyosis, especially of the legs.

DR. HAROLD N. COLE, Cleveland: The discussion of Drs. Oliver and MacKee is appreciated. It will be interesting to follow the succeeding siblings in this family and note what occurs. Thus far one girl aged 2½ years and another aged 6 months show nothing.

DR. J. T. SIMMONS, Erie, Pa.: It has now been approximately one and a half years since the cataracts were operated on. With corrective bifocal lenses both children now walk about freely, in contrast to their being content to sit still before. They now have an increased vocabulary and recognize common household articles and toys by name, indicating that the visual apparatus is functioning. The squint has shown no improvement to date.

DR. HORACE K. GIFFIN, Cleveland: Not only the physical defects of ectodermal origin but retarded mental development in these children complete the picture of involvement of the whole embryologic ectoderm which includes the nervous system. Mental changes in such cases reported seem to be as rare as the cataracts found in the eyes. These cases then are unique in the completeness of ectodermal involvement with even slight mesodermal defect as well. There is scanty evidence for hereditary transmission here, but such similarity of findings in sisters together with similar cases reported elsewhere make it probable. Periodically the blame for certain types of anomalies has

been placed on infections in the endometrium of the mother, but the evidence for this is probably inadequate. It would be hard to prove or exclude endometrial chemical changes causing abnormal development. Smith and Gault in their "Essentials of Pathology" indicate that present theories for the cause of anomalies rest chiefly on mechanical factors. The birth of apparently normal children following these 2 reported does not exclude the probability of intrauterine infection, but we have no positive evidence to indicate it. However, it is probable that the damage to the ova must have occurred very early in their development.

DISSEMINATED CONGENITAL OSTEOMAS OF THE SKIN

WITH SUBSEQUENT DEVELOPMENT OF MYOSITIS OSSIFICANS

REPORT OF A CASE IN AN INFANT

FRANK VERO, M.D.

GERALD F. MACHACEK, M.D.

AND

FREDERIC H. BARTLETT, M.D.

NEW YORK

Osteoma as a congenital abnormality of the skin is not generally known although its development from embryonal cell rests has occasionally been suggested. Our purpose in this paper is to report a case of osteomas occurring in an infant, which is especially rare and may therefore add to the knowledge of the nature of congenital heterotopic bone formations.

Osteoma has been defined as a new growth composed of bone tissue, benign in nature, without any tendency to invasive growth or metastasis. Osteomas have been found in practically all organs as well as in the skin. Osteoma of the skin has been variously reported as "osteosis cutis" by Arzt¹ and Becker,² "osteoma cutis" by Taylor and MacKenna,³ "osteomatosus cutis" by Dietrich,⁴ "miliary osteoma" by Hopkins,⁵ "chondro-osteoma" by Carl⁶ and many other titles. Few of the reported cases can be considered as true or primary osteomas, that is, in which all component parts throughout the tumor consist of bone tissue. Many are secondary ossifications according to Borst,⁷ and may have originated from injuries, inflammatory processes or tumors and the like.

REVIEW OF THE LITERATURE

Osteomas have been mentioned in the earliest literature. They were described as stony, bony substances, calculi or tophi, but a more precise differentiation dates to 1858 (Wilkins's⁸ dissertation). Since this publication the literature has been reviewed by Strassberg,⁹

Naegeli,¹⁰ Becker,² Hopkins⁵ and others. No mention is made of osteoma in Cockayne's book of "Inherited Abnormalities of the Skin and Its Appendages" or in Pfandler and Schlossmann's¹¹ "Hautkrankheiten des Kindesalter." In the literature we were unable to find a description of cutaneous osteoma in the newborn. In the frequently cited Keiler¹² case the presence of cutaneous bone formation was not demonstrated. The pathologic findings were interpreted by Simpson as a possible "ichthyosis intransienta," a form of cutaneous congenital disease. The original clinical description and the colored drawing of this premature newborn infant are more suggestive of a monstrosity or malformation.

Taylor and MacKenna³ observed osteomas in a 15 month old infant, which were first noticed by the mother when the offspring was 5 months of age. A large plaque was present on the knee and smaller ones on the anterior chest wall and on other parts of the body. The pathologic findings were those of bone tissue without any cartilage.

Coleman¹¹ described a case of "osteosis" in a 6 year old child which appeared at 3½ years of age and involved one third of the external plantar surface of the left foot.

Heidingsfeld¹⁶ found osteomas in a pigmented hairy nevus on the chin of a 21 year old man which had been present since birth. He considered the association of osteoma with a pigmented nevus, which admittedly is of congenital origin, significant and believed that the osteoma originated from displaced embryonal cells.

Carl⁶ excised a hazelnut-sized, flat, hard tumor from the neck of a 22 year old man. Its presence was first noticed at 2 years of age, grew until the age of 6 and then remained stationary. The microscopic examination showed typical bone structure, cartilage and calcified cartilaginous groundsubstance. He believed that the tumor was a chondro-osteoma which was derived from dispersed embryonal cells with the potentiality of forming chondromatous or osteomatous tissues.

In 1911 Strassberg⁹ published his observations on heterotopic bone formations, based on 6 cases he had studied in his autopsy material at the pathologic institute of Vienna. These seemed to be secondary osteomas, with the exception of 1 case. The first case developed in a laparotomy scar, the second in a varicose complex of the lower leg following hemorrhage and deposit of calcium. In 3 cases bone formation was found in association with a dermoid cyst and epidermoid carcinomas. He thought that in only 1 instance was the development of the osteoma explainable as originating from aberrant embryonal cells. This osteoma was situated in the galea aponeurotica not connected to the periosteum or the skin above. No trauma or other pathologic condition preceded the bone formation and no calcium deposits could be found.

In 1924 Becker² reviewed bone formations and reported a case he observed in a 32 year old woman. He described a large triangular plaque situated in the

Drs. J. P. Caffey, H. L. McLaughlin and A. P. Stout gave cooperation and advice.

another publication dealing with true osteomas he reported 2 cases on the basis of the history and histologic findings, although in 1 of these the osseous tissue was found in a "carcinosarcoma."

A very unusual case was described by Dietrich,⁴ in which a 42 year old Negress had a peculiar growth on a finger since early infancy. It measured 1.5 by 1.5 cm. and contained 15 to 20 nodules of bone. It impressed him at first as a sesamoid or supernumerary digit, but after further observation and histologic interpretation of Dr. Weidman, he believed that the tumor-like swelling was a congenital abnormality, possibly a bony nevus.

A recent case of osteoma cutis in a 25 year old man was reported in 1941 by Paavo Pirilä.¹⁷ It was of two years' duration and measured 3.5 by 2 cm., barely rising above the skin surface, and was freely movable over the frontal bone. The microscopic examination showed that the osteoid tissue present resembled that found in embryonal bone formation. Pirilä felt that the findings justified the diagnosis of true osteoma of congenital origin and nevus in character.

REPORT OF CASE

History.—C. S., a boy aged 2½ years, was first seen by one of us (F. H. B.) when 19 days old and again at 3½ months. The mother stated that immediately after the baby was born she noticed small, peculiar "bumps" on the left side of the scrotum, on the left leg and on other parts of the body. These were also observed by her obstetrician. The lesions increased in size within the next few weeks with new ones appearing on the body, left lower extremity and back.

The family history was negative. No similar skin disorder was present in the parents and 2 older brothers. The mother enjoyed good health during her pregnancy. She stated that she had not taken calcium, vitamin D or any other drug. Her delivery was normal. The baby's birth weight was 7½ pounds (3,400 Gm.).

Physical Examination.—At 19 days of age the following notes were made: The heart, lungs and abdomen were normal, as were the measurements of the head, chest and height. The skin, however, of the left side of the scrotum, between the scrotum and the left thigh, showed a peculiar lumpy plaque measuring about 1.5 by 2.5 cm. which felt like thrombosed blood vessels. Lymphangioma was the diagnosis made at that time. At 3½ months of age, nodules were felt under the skin of the back, left thigh and ankle regions. The baby was then seen by the senior author.

17. Pirilä, Paavo: Ueber Hautosteoma: Ein Fall von echten Hautosteom, *Acta dermat.-venereol.* 22:360, 1941.

Examination of the skin showed a large number of widely disseminated, solitary and grouped, small papular and nodular lesions and irregularly outlined plaques. They were strikingly numerous in the left genito-crural region, on the lower half of the scrotum and the groin and on the left thigh and lower part of the leg, where they involved both the anterior and

FIG. 4.—Appearance of pelvic region; note opacities in left side of scrotum.

posterior aspects. Numerous lesions were scattered throughout the back, diminishing in number on the trunk and upper extremities.

The individual lesions varied in size from 1 to 5 mm. in diameter, the coalescing plaque on the scrotum measured 1.5 by 2.5 cm., those on the back and left ankle 2 by 3 cm. Their color was variable, ranging from pearly white to a light yellow and from flesh color to a faint red or dull brown. Many of the lesions were distinctly raised above the skin surface 1 to 4 mm. Other lesions were level with the skin surface. The presence of many could be ascertained only through palpation, and in some areas on the back they gave the impression of extending into the deeper layers of the skin. The consistency of the lesions was firm, hard and gritty. The larger plaques were resilient, elastic and after being folded between the fingers resumed their shape instantly. They were firmly attached to the skin but were freely movable over the underlying tissues.

The most unique changes were in the genito-crural region, where a large yellowish white irregular plaque was seen, consisting of closely grouped unequally raised lesions forming furrows and puckers in the involved skin. This closely simulated the "frog spawn" appearance of lymphangioma. The clinical appearance of the scattered small lesions as to size, shape and color was that of milia. The larger ones simulated cysts, except for their stony hardness (fig. 1). Meanwhile a biopsy was taken, which on microscopic examination proved to be an osteoma.

Course.—The baby was seen again when 11 months old, after spending the winter in the South. His growth and development during this time were normal. The mother thought that many lesions had undergone changes, some having become smaller, others larger. The child was then admitted to the Babies' Hospital for observation and further investigation. At this time there was an apparent involution of the lesions of the left groin, scrotum, thigh and back. The plaques were less raised, and areas previously involved showed evidence of some atrophy. These changes were more pronounced on the trunk

and especially on the abdomen, where a large number of round and oval soft and slightly depressed white and flesh colored, macular atrophic lesions measuring 5 to 10 mm. in diameter could be seen without any evidence of stony nodules. There were similar though smaller atrophic lesions present on the thigh, in the center of which one could detect the presence of deep seated milium cysts but only through palpation and visualization by x-rays. The only other change during the past year and a half was an occasional spontaneous perforation of the skin with extrusion of a small concretum easily removable by forceps. This occurred mainly on the toes, which at these times became reddened, swollen and tender. After the removal of the concretum and application of wet compresses of cold boric acid solution the inflammatory changes subsided, leaving a slight pigmentation.

Microscopic Examination (G. F. M.).—The first biopsy specimen, consisting of two small pieces of skin, was removed from the back on Nov. 5, 1942. The epidermis showed no evident changes. Within the corium of both pieces were fragmented trabeculated bluish masses. Embedded in this calcified tissue were shrunken cells containing pyknotic nuclei. The reticulated pattern of its osseous trabeculae enclosed a loose fibrillar vascular tissue, spindle shaped cellular elements and fat cells. The corium had been replaced in part by bone containing both osteoblasts and marrow. Correlating the histologic morphology with the clinical description, a diagnosis of multiple congenital heterotopic osteomas was made.

On June 10, 1943 a second piece of skin was excised from the left ankle. Numerous preparations were made and examined (figs. 2 and 3). The epidermis showed a slight hyper-

FIG. 5. Disseminated opacities in skin of lower part of left leg.

keratosis. Parts of the corium had been replaced by a cellular fibrous tissue. Numerous osteochondromatous trabeculae had formed. These extended from beneath the epidermis, from which they were separated by collagen down to the fat lobules. The more centrally placed areas of the trabeculae were calcified and enclosed relatively large spaces which contained cells with pyknotic nuclei. The trabeculae were rimmed by an eosinophilic

border, within the substance of which were shrunken cells morphologically osteoblasts. The chondro-osteomatous masses contained several multilocular cysts partly filled with eosinophilic amorphous material. These cysts were walled by a condensation of fibrous connective tissue and in part by numerous spindle and cuboidal cellular elements which resembled osteo-

Fig 6.—Grouped cutaneous opacities in left side of back.

blasts. The few multinucleated cells were thought to be osteoclasts. The interstices between the bony trabeculae contained a vascular finely fibrillar connective tissue with fat cells. This was evidently bone marrow. Tiny islands of eosinophilic osteoid tissue such as rimmed the larger cartilagenous elements were in the deeper corium and in the fat lobules. The intracuticular bone appeared to be derived from both cartilage and connective tissue.

Other sections were stained with Masson's trichrome, von Kossa's silver impregnation and Perl's methods. No keratinizing epithelial cells were demonstrated in the walls of the cysts. There was very little evidence of the presence of calcium phosphate; in fact, the hematoxylin eosin stain demonstrated calcium more adequately than the silver impregnation method. The prussian blue reaction was essentially negative throughout the sections. Microscopic examination failed to disclose the presence of blood pigment or hemorrhage.

The lesion was diagnosed as a heterotopic chondro-osteomatous formation with necrosis. Interpreting the histologic morphology, it was assumed that the tumor was composed of young developing osseous tissue.

A third specimen, which consisted of a firm cutaneous extrusion, was obtained on Feb 15, 1945. Microscopic examination of sections disclosed necrotic, partially calcified trabeculated chondro-osseous tissue surrounded by numerous polymorphonuclear leukocytes. A shred of thick keratinized epidermis was attached to the bone. The lesion represented a necrotic heterotopic osteoma.

(All specimens were fixed in solution of formaldehyde U. S. P. diluted 1:10 and except for the first were decalcified.)

A concrement which had been extruded from one of the child's toes was reported as an "exostosis" by another pathologist.

Roentgenograms (figs. 4, 5, 6 and 7) of long bones with special films for soft tissue were examined by Dr. Caffey, who reported that in several areas of the skin, particularly those of the left lower extremity, perineal region and lumbar level of the back, there were scattered shadows of calcium density. These varied from the large plaques on the left side of the scrotum several centimeters in diameter to numerous pinpoint and pinhead calciferous foci in the lower extremity. In all projections where these foci were seen in profile they were superficially placed apparently just under the epidermis. There were no pathologic changes demonstrable in the bones. In anteroposterior and lateral roentgenograms of the skull no pathologic changes were visible. Dr. Caffey felt that these disseminated calciferous lesions in the skin warranted a roentgenologic diagnosis of "calcinosis universalis."

Laboratory Examinations.—Hemoglobin was 12.8 Gm, red blood cells numbered 4,600,000, white blood cells numbered 9,800, with 42 per cent polymorphonuclears, 52 per cent lymphocytes, 4 per cent monocytes and 2 per cent eosinophils. Chemical examination of the blood revealed nonprotein nitrogen 36.3, calcium 11.3 and phosphorus 5. Phosphatase was 89. The Kline test was negative. Tuberculin, 0.01 mg., gave a negative reaction.

DIAGNOSIS

The difficulty in making a clinical diagnosis of osteoma of the skin is admitted by all authors dealing with the subject. The diagnosis is usually established

Fig 7.—Scattered cutaneous opacities in right upper extremity.

only after biopsy and subsequent microscopic examination. A stony, resilient, cartilaginous or calcareous consistency felt on palpation is frequently mentioned as the deciding factor in performing a biopsy. Roentgenograms may be of aid in the diagnosis as they show opaque shadows or structureless densities, thus detecting lesions which escape inspection and palpation.

Osteomas appear in both sexes and when found in the young are usually considered to be true osteomas. The scalp, forehead, cheeks and chin seem to be the more frequent locations, although they may occur on any part of the body. They may be present as solitary or multiple lesions, but a dissemination is infrequent. Their size may be that of a poppyseed or a large bean. Those described as plaques may measure several centimeters in diameter and usually consist of an aggregation of many bony nodules. The color of the lesions is not very characteristic, since they may be flesh colored, pearly, reddish, brown or purplish. Some lesions are raised above the skin surface, others are level with it. They may be round, oval or irregularly contoured but are usually sharply outlined. The surrounding skin is normal. The skin above the lesions may be atrophic or cicatrized. An inflammatory redness occurs, with spontaneous extrusion of bony particles.

Subjective sensation is absent and no tenderness is elicited in the uncomplicated case. Many of the patients seek medical advice only after the lesions have per-

Fig. 8—Lobulated bony tumor of the left buttock

sisted for years and usually for cosmetic reasons or because of frequent traumatization.

Microscopic studies are indispensable in the diagnosis. This is the only means by which osseous tissue can be identified. In the differential diagnosis consideration must be given to calcinosis cutis and to secondary ossification.

Without exception all authors agree that surgical excision of the osteomas is the only successful therapeutic measure.

COMMENT

Many cases reported in the literature as true osteomas have not been accepted as such. Naegeli¹⁰ accepts only 6 cases as true osteomas of those published up to 1935. The others he considers secondary ossifications.

Secondary ossifications following various pathologic processes of the skin are more frequent and are presumed to be metaplastic. They have been observed occurring in syphilitic and tuberculous granulomas, scleroderma, acne, lupus erythematosus, granulation tissue and scars, especially in those following laparotomies and burns. In this group also belong ossifications, which develop after trauma, hemorrhage, thrombosis and fat necrosis as well as in retention cysts, dermoids and in tumors such as lipomas and carcinomas. None of these ossifications should be regarded as congenital cutaneous anomalies.

The diagnosis of true osteoma may be accepted when it occurs in early life or when found in nevi and when not preceded by other pathologic changes in the skin. Here the microscopic examination may be of aid as far as it discloses the absence of a preceding pathologic condition. From the histologic morphology of the osseous

Fig. 9—Section of osseous tumor from muscle under low power show ing cartilage, bone and marrow

tissue one cannot draw definite conclusions as to the primary or secondary nature of the osteogenic process.

True or primary osteomas are believed to develop from dispersed embryonal cells. The possibility that osteomas may arise from displaced bone fragments has been mentioned in some of the reported cases. The bone tissue found in some mixed tumors and malformations are probably true osteomas. The theory has been advanced that cutaneous osteomas may be a form of atavism.

Fig. 10—Specimen shown in figure 9 under high power, with adherent muscle fibers

The presence of practically all the lesions at birth or soon after in our case indicates that we are dealing with true primary osteomas of the skin. We considered the possibility of some inflammatory or other pathologic process occurring in the skin during intrauterine life which may have preceded the development of the osteomas. Physical, roentgenologic and laboratory exami-

nation, however, did not disclose any systemic or cutaneous disease whatever. Furthermore, many lesions developed after birth and at no time were any other changes observed in the skin. It is obvious that the cutaneous osteogenesis in our case is of congenital nature, and it may be presumed that this resulted from dispersed embryonal osteogenic cells. This view is in accordance with Cohnheim's¹⁸ theory of the endogenous origin of congenital tumors.

Correlating the microscopic morphology of the specimens examined with the clinical manifestations, it may be concluded that the tumors are congenital, disseminated, heterotopic and chondro-osteomatous. As the lesions are circumscribed they are to be considered nevi. The absence of preceding pathologic change indicated their primary character. Clinical observation showed that the tumors had the property of independent growth. Because of the extrusion of bony nodules and the presence of necrotic cystic changes within the osseous tissue of one of the specimens a careful examination for the presence of epithelial cells was made. Secondary ossification frequently occurs in the presence of keratinizing cells and sebum filled cysts. None were present.

Of hemorrhage, which may initiate calcification and ossification, there was no evidence. No extravasated red blood cells and no hemosiderin granules were seen. The tissues were, in fact, poor in demonstrable iron.

The osseous tumors appeared to arise in part from connective tissue elements. This intramembranous type of ossification one would expect to occur within the cutis. The fact is, however, that most of the osseous tissue appeared to be an endochondral bone formation.

In view of these observations, namely that the lesions originated during fetal life and that they were predominantly chondro-osteomatous, it should be remembered that there is a definite progression in the process of fetal ossification. Precartilaginous connective tissue is formed from a condensation of mesenchymal elements which are replaced by hyaline cartilage. The matrix of the cartilage becomes impregnated with calcium salts and is ultimately replaced by osseous or osteoid tissues. This progression is suggested by the histologic morphology of this case.

It would be simpler to explain the bone formation in our case by the more generally held hypothesis that all connective or supportive tissues are closely related and that each type may under certain conditions acquire the potentialities of the others. That is to say that collagenous connective tissue, cartilage, bone and fat are capable of such transformation. Cartilage cells lying within their matrix may contain fat globules. Bone cells grow as fibroblasts and may be transmuted in vitro or in vivo osteoblasts or chondroblasts under appropriate conditions.

As we demonstrated roentgenologically that the tumors bore no intimate relation to the tendons and joints and that in the histologic preparations there was no evidence of xanthomatosis, we rejected their sesamoid bone origin.

SUMMARY AND CONCLUSIONS

In an unusual case of congenital and disseminated osteomas of the skin in an infant the osteomas were seen immediately after birth on the scrotum and the trunk but were most numerous on the left lower extremity.

The osteomas in our case were considered as true or primary congenital tumors of the skin, originating

presumably from the dispersion and displacement of embryonal tissue cells. They are to be regarded as one of the rare developmental abnormalities of the skin: bony nevi.

ADDENDUM

Since this paper went to print C. S., aged 2 years and 11 months, was readmitted to the Babies Hospital on June 8, 1945. A number of the cutaneous nodules had disappeared following extrusion of osseous fragments. Two months before readmission the mother noticed hard masses in the left popliteal region and the left buttock. These were deeply seated and had evidently involved the musculature. Examination disclosed that external rotation and extension of the left thigh were limited because of the mechanical interference of the tumor of the buttock. Although the child's usual activity was in no way impaired, the musculature of the thigh and buttock was diffusely and slightly atrophic and weaker than normal. No brachydactylia or other anatomic anomaly of the hands or feet was present. A roentgenogram revealed "a large irregularly calcified mass visible lateral and posterior to the hip joint" (fig. 8).

At operation the trilobate mass of the buttock proved to be "half again as large as represented by the x-ray shadow." There was no connection between this tumor and the femur; it was, however, adherent to the ischium. This attachment was not direct but only due to soft part connection, in the words of Dr. Harrison L. McLaughlin, the surgeon, "mainly by the origin of the hamstrings." The ossification involved "the external rotators of the hip and hamstring origins" and "probably the adductor minimus. The gluteus maximus was uninvolved." The lateral lobe of the tumor, about the size of a golf ball, was ablated and presented to Dr. A. P. Stout for pathologic examination. He found the specimen to be a "pyramidal piece of bone and cartilage." Dr. Stout's microscopic description follows:

Sections showed that the nodule was made up of well differentiated bone containing marrow and masses of hyaline and fibrocartilage. Along one margin was a little striated muscle. The muscle did not appear to be included within the bony growth. All of the tissues were well differentiated and the foci of most active growth appeared to be signaled by the presence of large groups of capillaries.

This picture is not exactly like the ordinary myositis ossificans, first, because cartilage is formed freely, and, second, because the process of ossification does not seem to enclose within itself isolated muscle fibers. It seems evident that this must be a case of profound disturbance of the bone and cartilage forming mechanism, which had resulted in the formation of bone and cartilage in the skin and in the muscle. The lesion more closely resembles progressive myositis ossificans than any other lesion with which I am acquainted. We will therefore tentatively classify it as such. Diagnosis: Myositis ossificans progressiva.

Rosenstirn,¹⁹ in a case of myositis ossificans progressiva described "two very small spiculae of bone directly in the skin; one on the right arm near insertion of deltoid muscle in outer groove, the other in the popliteal fossa of the right leg." These were excised with the skin, and microscopic examination disclosed the presence of osseous tissue.

ABSTRACT OF DISCUSSION

DR. S. W. BECKER, Chicago: The authors have made an excellent presentation of an interesting and, fortunately, rare dermatosis, which has been designated "osteoma cutis" or "osteosis cutis." When I used the latter term in presenting the case of a woman with a large plaque on the scalp, I did so because the disorder was not considered merely as a neoplasm but rather as replacement, possibly atavistic, of connective tissue by true bone in a considerable area. The designation "osteoma" seems more appropriate for the small globular tumors as reported by Hopkins and others. I recently observed a woman aged 65 who presented tumors on each side of the chin which had been present for many years but had increased in number during the past year. They were firm and superficial, and the smaller ones had the whitish color of milia. When incised, stony resistance was encountered which signified the presence of calcium or bone. Microscopic examination of several masses which were shelled out showed that they consisted of osseous tissue. The location in an area which is often involved in comedones and cysts as part of acne vulgaris suggested preexistence of some such lesion. However, lack of a history of these and the age of the patient made such a sequence of events improbable. The diagnosis of osteoma cutis still rests on microscopic examination, and the only satisfactory treatment is surgical. The disorder is seen so seldom and the case reports are so different that, while the condition may be considered a definite entity, etiologic considerations are still conjectural. When bone formation follows calcification or occurs in tumors, abnormal conditions are apparent and are presumably causative. Whether the same abnormal conditions precede growth of bone in seemingly normal dermis is unknown.

EPIDERMOLYSIS BULLOSA IN
THE NEWBORN

ROBERT A. BLACK, M.D.
EMMANUEL WILHELM, M.D.
CHARLES S. GILBERT, M.D.
AND
CLEVELAND J. WHITE, M.D.
CHICAGO

Bullous syndromes in the newborn are not common except in epidemics of impetigo contagiosa (pemphigus neonatorum). The latter is comparatively easy to diagnose, and the usual therapy is successful. Proper prophylactic measures are immediately instituted once the diagnosis is made. The other bullous entities are rare and at times difficult to diagnose immediately, except in the congenital syphilids. A recent opportunity was afforded to study a case of congenital bullous eruption from birth to death. This was the third baby in the family with a bullous eruption and fatal outcome. A clinical diagnosis of epidermolysis bullosa was finally made. The histologic picture was considered by two dermatologists to be diagnostic of the syndrome and by a third with similarly large experience as a bullous syndrome that was compatible with this diagnosis but not diagnostic of it and possibly fitting in with a congenital ectodermal defect.

REPORT OF CASE

M. F. S., a boy baby weighing 8 pounds 4½ ounces (3,630 Gm.), was born Sept. 16, 1944 with bullae on the dorsal surface of the distal phalanges of each index finger. The hands were distended with clear fluids and had an erythematous

areola. The baby was observed directly after birth because of the history of the mother that the two previous babies had died soon after birth, each having had a blister-like eruption. The parents had been observed three months before the birth of this baby and were found to be normal. Within eighteen hours after birth these bullae collapsed, leaving erythematous

Fig. 1.—Baby's hands eighteen hours after birth.

borders (fig. 1). Small erythematous bullous lesions were now noted on the forehead and eyelids. The baby was given 3,000 units of penicillin intramuscularly every two hours, and a local application of penicillin, 250 units per cubic centimeter, was made to the lesions on the skin. The patient was afebrile at this time.

Artificial feedings were begun on the second day after birth.

Smears of the lesions about the eyes revealed gram positive diplococci, which on cultures were found to be nonhemolytic staphylococci.

The lesions seemed to improve temporarily with the penicillin, but by the fourth day they began to spread over the back in the right scapular region, buttocks, both knees and elbows, and eventually over the whole trunk. Penicillin dressings were discontinued ten days after birth, and 5 per cent sulfathiazole cream was used locally. Penicillin was given intramuscularly every three hours in doses of 1,000 units. Small repeated transfusions of whole blood were also given. Eventually the lesions were very extensive, involving the face, trunk and extremities, and they were then painted with 2 per cent gentian violet.

Approximately one month after birth, paronychia developed with the loss of fingernails and toenails. There was thought to be fairly good response to the gentian violet one week after its institution, the older lesions were drying and there were no new ones noted. A few days later the child began to have difficulty in retaining his formula, and difficulty in breathing was noted. Examination of the throat revealed numerous raised bullous lesions, with several collapsed bullae in the oropharynx. At 40 days of age he had an episode of respiratory

Fig. 2.—General involvement of the skin two months after birth.

obstruction, which was relieved by suction. This was thought to be due to inhalation and plugging by some of the sloughed bullae, as the oral cavity was now involved.

A phytotoxic test revealed 48 units, indicative of a toxic dermatosis possibly in the erythema multiforme group. The Nikolsky sign was negative and remained so. Photographs (fig. 2) of the patient were exhibited at the meeting of the

Paper in a symposium on Congenital Disorders Involving the Skin, published under the auspices of the Section on Dermatology and Syphilology.
From the Departments of Pediatrics, Obstetrics, Medicine and Dermatology, Loyola University School of Medicine, 706 South Wolcott Avenue, and the Loyola University-Mercy Hospital Clinics, 2526 South Calumet Avenue.

Chicago Dermatological Society on November 15, and a very liberal discussion centered about the four most common possible syndromes, namely congenital epidermolysis bullosa, bullous erythema multiforme, impetigo contagiosa of bullous type and pemphigus vulgaris, and suggestions were offered for therapy.

Repeated small transfusions were again given, with transient improvement. At this time a biopsy was secured of new and old bullous lesions. Histologically there were areas of inflammatory hyperplasia at the sites of erosion. About this time the baby began to develop an intermittent type of fever, varying from 103 to 106 F. with corresponding increases in the pulse and respiratory rates. The course was progressively downward with the development of a subnormal temperature, until seventy-four days after birth.

At birth the blood examination showed 5,520,000 erythrocytes, 16.5 Gm. of hemoglobin and 17,600 leukocytes, with 56 per cent polymorphonuclears, 42 per cent lymphocytes and 2 per cent monocytes. A subsequent examination revealed 4,500,000 erythrocytes with 8,450 leukocytes and a differential distribution of 40 per cent polymorphonuclears, 51 per cent lymphocytes, 4 per cent eosinophils and 5 per cent monocytes. Near death the erythrocytes dropped to 3,850,000, with 10.5 Gm. of hemoglobin, 13,200 leukocytes and a differential count of 48 per cent polymorphonuclears and 52 per cent lymphocytes.

The family history revealed the mother to be 27 years old and apparently perfectly healthy. The father was 30 years of age and well except for a cataract of the left eye. There was no past history of tuberculosis, syphilis, diabetes, cancer, renal disease or blood dyscrasias. The maternal mother died of heart disease at 55 years of age. The mother had given birth to four other children, the first a boy, born July 31, 1935, who died of a ruptured appendix on Feb. 15, 1940; the second, a girl born on Oct. 26, 1936, who died of "congenital pemphigus" on Nov. 26, 1936; the third, a boy, born Aug. 9, 1939, who is living but has a bilateral inguinal hernia; the fourth, a boy born May 1, 1941, who died on May 30, 1941 of apparently the same disease that affected the second child and the patient described in this report.

The mother's puerperium was essentially negative after all these deliveries. She was examined periodically before the birth of this child, but no cutaneous abnormality was found. The father was examined and nothing found of any importance either generally or dermatologically.

An autopsy was performed. The baby was found to have, in addition to the widespread cutaneous eruption consisting of eroded areas and large dried bullae, pulmonary atelectasis and a patent foramen ovale. The body was characterized by dehydration and cachexia.

COMMENT

Davidson¹ recently reported a case of hereditary epidermolysis bullosa and reviewed the literature in great detail. In 1902 Luithlen² gave a comprehensive review of the subject up to that time, together with excellent descriptions of the two generally recognized types of the disease, the simple and the dystrophic. These descriptions may be summarized briefly as follows:

In the simple form the bullae appear on the skin after mechanical irritation or slight trauma. The disease is usually congenital; the lesions may be present at birth or may appear first from a few days to two or three years after birth. The mucous membranes are not affected, and the nails are not involved. The blebs heal without leaving scars, and there is no permanent alteration in the skin. The general health of the patient remains unaffected, although the disease may persist indefinitely. In some cases the tendency toward the formation of bullae ceases at a later age, often at puberty.

In the dystrophic form the hereditary nature of the disease is present but is not as pronounced as in the simple form. The condition usually persists through life. The bullae appear at or soon after birth, as in the first form, and arise after trauma. They are most apt to become hemorrhagic. In healing crusts and scabs are formed, resulting in permanent pigmentation and scarring. Occasionally, deep ulcerations occur, but usually the skin shows atrophy, wrinkling or an ectodermic condition. The skin may be thickened and crusted, especially over the knees and elbows. Thickening may be due also to horny cysts embedded in the skin. These resemble milia and either are scattered over the surface or appear in circumscribed groups. The cysts may disappear spontaneously after several weeks, or they may persist indefinitely. Itching may precede the formation of bullae or may be absent. Extensive degeneration of the nails is a constant characteristic of this type. The nails may be absent at birth or be shed soon afterward. When present they are always thickened and deformed, lamellated and without luster. The buccal mucosa and the tongue show bullae, ulceration and leukoplakia, and there may be scarring of the lips. The tongue may be atrophic.

The observation of different investigators on the pathogenesis of hereditary epidermolysis bullosa shows considerable variation and contradiction. That there are a more or less constant reduction and degeneration of the elastic tissue of the skin is pretty well agreed. Practically all investigators believe that the bullae may be ascribed to a modified susceptibility or reactivity of the skin to injury, to an increased irritability of the integument which under normal conditions would result only in transient hyperemia. Some observers (Elliot,³ Unna,⁴ Torok⁵) express the opinion that there is a congenital irritability of the vascular system of the skin, with the result that the basal portion of the rete is bathed in a serous transudate, undergoes degenerative changes and finally becomes detached from the connective tissue. Others, particularly Engman and Mook, ascribed the formation of bullae to congenital absence of or defect in the elastic tissue of the papillary and subpapillary layers of the skin, with edema of the succulent horny layer and colliquation of many cells in the basal layers of the epidermis. These authors regarded the absence of elastic tissue as a primary phenomenon, while Bock and others believed that the disappearance of elastic tissue results from degeneration, which in turn is provoked by persistent edema of the upper part of the corium.

Finally in 1934, in a long and detailed paper, Herlitz⁶ described a new, so-called lethal form of the disease which he termed "epidermolysis bullosa hereditaria letalis." He recognized the two main types previously described, i. e. the simple and the dystrophic form. Out of an extensive review of the literature, which was complicated by absence of uniform terminology and of strict criteria for diagnosis, Herlitz brought together 22 cases of the new forms: 8 of his own, 3 of Mautner's,⁷

2 of Kuse's,⁸ 7 of Jenny's⁹ and 2 of Heinrichsbauer's.¹⁰ The condition in the cases of this group differs from the classic, simple and dystrophic form in that it always leads to early death, which usually occurs before the third month. In no case was the duration longer than seven and one-half months. Herlitz's 8 cases occurred in three families, 4 in one and 2 in each of the others. In no instance had there been a previous case in any of the families, all of which came from the province of Uppland in Sweden and whose records went back to the beginning of the eighteenth century. The presence of extensive congenital cutaneous structures, especially the tendons and blood vessels, were readily visible through the transparent tissue. The Nikolsky phenomenon (rubbing off of the skin in the bath) was present but it was not possible to produce vesication by deliberate trauma, such as rubbing, pinching or bandaging. There were pronounced dystrophy and deformity of the nails, some of which were absent at birth or fell off soon afterward. In some cases these lesions progressed to involve severe skeletal atrophy of the terminal phalanges. Histologically there was degeneration of elastic tissue, the skin was thinner than normal and the sweat glands and hair follicles were rudimentary. The author differentiated this condition from congenital syphilis and from congenital pemphigus neonatorum.

The case here reported seems definitely to belong to the small group described by Herlitz,⁶ which he called epidermolysis bullosa hereditaria letalis. The congenital cutaneous bullae on the two fingers at birth are typical of this disease. The subsequent involvement of the whole integument and the mucous membrane of the mouth, tongue and pharynx, the rapid and widespread formation of bullae, with secondary infection and constitutional debilitation resulting in early death, are characteristic of the so-called lethal form of hereditary epidermolysis bullosa.

SUMMARY

Bullous eruptions in the newborn (save for impetigo contagiosa) are uncommon. Epidermolysis bullosa can occur and, in the lethal form, bullae arise irrespective of trauma or irritation. The eruption is progressive and soon is fatal, irrespective of therapy.

ABSTRACT OF DISCUSSION

DR. RUBEN NOMLAND, Iowa City: Several years ago I had the opportunity of observing a case almost identical with that of the authors and I believed it to be the lethal form of epidermolysis bullosa. The skin of a newborn baby slipped off in large areas during delivery. Subsequently many spontaneous blisters formed and the infant died. Postmortem examination revealed nothing of significance except for the skin, in which the epidermis was separated from the dermis. In the newest blisters the papillae at the floor of the blister projected into the blister cavity and the corresponding rete pegs projected downward. This would indicate that the essential pathologic condition was that of lack of cohesion between the dermis and epidermis. I do not believe that the loss of elastic tissue is the most important factor in this separation. First, blisters do not occur in those diseases in which there is loss of elastic tissue, the best examples being idiopathic atrophy and the various forms of scleroderma. Second, personal examination of several cases of epidermolysis bullosa, particularly with connective tis-

sue stains such as Van Gieson's, has shown that in this disorder the collagen fibers are less firmly attached to the basal cells and rete pegs than in normal skin. The lack of cohesion between the dermis and the epidermis in epidermolysis bullosa is seemingly connected with loss of elastic tissue, abnormal connections between the connective tissue of the dermis and the basal cells, and probably other abnormalities not yet recognized.

THE TREATMENT OF EXTERNAL HERNIAS CONTAINING GANGRENOUS BOWEL

NEW METHOD UTILIZING THE MILLER-
ABBOTT TUBE

W. D. GATCH, M.D.

AND

W. FOSTER MONTGOMERY, M.D.

INDIANAPOLIS

Dr. Emory G. Alexander¹ in 1913 in a paper on strangulated hernia wrote "It is strange that in the past two decades of progressive surgery, an era unparalleled by great strides made in the art of diagnosis, operative technic and after-treatment—to say nothing of the help obtained by educating the public to surgical conditions—little has been done either directly or indirectly to lower the death rate of this condition." The results of the treatment of strangulated hernia are no better in 1945 than in 1913. A review of reports on strangulated hernia, published since 1913, shows that the results of treating this condition are as poor now as they were then; in fact, the death rate is about as high today as it was in the days of preaseptic surgery.

Many ingenious methods have been proposed for the cure of patients having gangrenous bowel in external hernias. The accompanying diagrams illustrate all these of which we have been able to find descriptions.

These methods have serious drawbacks. Several of them make necessary division of Poupart's ligament in order to reduce gangrenous, friable intestine. The permanent disability which this may cause has been passed off too lightly in the literature. Some of them make necessary the anastomosing of collapsed bowel to distended and obstructed bowel in a patient in poor general condition because of dehydration, starvation and bowel distention. The methods which require an enterostomy of some kind are unsatisfactory and dangerous. Introduction of an enterostomy tube through the femoral canal by way of the lumen of the gangrenous bowel is dangerous, and it may dislodge the gangrenous bowel or perforate it. It may enter the bowel distal to the obstruction. It may not relieve the obstruction even when it enters the distended bowel, because bowel which has been distended for a long time will not recover its power to contract short of five or six days.²

The tube will therefore drain only the loop of distended bowel immediately proximal to the hernia. All of these methods are unsatisfactory because they are followed by death in too many cases.

The senior author in 1942, called to treat a healthy, obese woman of 68 for a femoral hernia, strangulated for five days, thought of the plan of treatment described in this paper. This plan, briefly, consists of three parts:

1. Incision of the hernial sac together with the gangrenous bowel within it.

8. Kuse, K. H.: Ein Beitrag zum Krankheitsbild des Pemphigus hereditarius, Monatschr. f. Kinderh. 42: 513, 1929.

9. Jenny, E.: Ueber eine letal verlaufende Form von Epidermolysis bullosa hereditaria beim Saugling, Ztschr. f. Kinderh. 43: 138, 1927.

10. Heinrichsbauer, F.: Ein weiterer Beitrag zur Frage angeborener Hautdefekte (neuer ein familiäres letales Krankheitsbild mit Blasenbildung und angeborenen Defekten der Haut), Arch. f. Gynäk. 134: 673, 1928.

1. Alexander, E. G.: Strangulated Hernia: Report of 105 Cases, Ann. Surg. 58: 639, 1913.

2. Battersby, J. S., and Gatch, W. D.: Two Stages of Bowel Distention, Arch. Surg. 44: 108 (Jan.) 1942.

2. Deflation of the obstructed bowel down to the point where it is obstructed at the hernial ring with a Miller-Abbott tube. This restores it to a healthy condition and permits giving the patient liquids and soft foods by mouth, thus correcting starvation and dehydration.

3. Laparotomy done after the tube has been down for about a week through a low, paramedian incision; excision of the gangrenous bowel, and intestinal anastomosis; plugging of the femoral ring with omentum stitched to it; treatment of the abdominal wound with sulfathiazole after closure of the peritoneum.

possible objection is that it may be impossible to pass the Miller-Abbott tube. We have not had any difficulty doing this because of the skilful help of our roentgenologists, who have had but six failures to pass the tube in over 100 unselected cases of bowel obstruction.

REPORT OF CASES

CASE 1.—*History*.—Mrs. R. B. S., aged 68, was admitted to Robert Long Hospital on Nov. 4, 1942 because of the appearance, three days before admission, of a mass in the right groin.

The method has proved simple and safe by clinical trial. Patients in a moribund condition can be cured by it. It corrects the systemic derangements due to bowel distention. It restores the bowel to a healthy condition, so that the anastomosis is safe. It spares Poupart's ligament and makes possible the immediate cure, we believe in most cases, of the hernia.

The only cogent objection to the method is that it exposes the patient to the danger of general peritonitis from separation of the living from the gangrenous bowel at the femoral ring. Experience shows that this is not likely to occur. We have found the living bowel firmly attached to the femoral ring in all of our patients. A

Persistent vomiting had ensued. No bowel movements occurred following numerous enemas and administration of castor oil and other cathartics.

Examination.—The patient was acutely ill, her face brick dust color, her tongue dry, her skin loose. The abdomen was distended, everywhere tympanitic and silent. The skin of the abdomen was blistered by hot applications. There was a large, acutely tender swelling in the right groin. The skin over this was fiery red and edematous. The pulse rate was 86, the respiratory rate 26, the temperature 99.6 F., the blood pressure 138/70 and hemoglobin 13.5 Gm. Red blood cells numbered 4,500,000, white blood cells 16,400.

Treatment and Result.—The patient was given a preliminary injection by vein of isotonic solution of sodium chloride and

glucose. An incision was made parallel to and below Poupart's ligament over the most prominent portion of the swelling. The bowel was found totally gangrenous and foul. Penrose drains were inserted. A Miller-Abbott tube was passed a few hours after operation. This was in the jejunum in forty-eight hours and had reached the site of obstruction in seventy-two hours. The patient was given liquids and soft foods by mouth for seven days. She was then operated on for the second time. A short, very low, paramedial incision was made. The end of the tube was resected, and a short lateral anastomosis was done to unite the two severed ends. The omentum was stitched to the edge of the femoral ring. Penrose drains were inserted into the femoral canal. The abdominal wound was closed. Sulfathiazole was sprinkled over the wound surfaces after the peritoneum had been sutured. The patient had a bowel movement on the

Examination.—The patient was a very obese woman, acutely ill and severely dehydrated. The pulse rate was 110, the respiratory rate 28, the temperature 100.2 F., the blood pressure 140/75 and hemoglobin 15.5 Gm. Red blood cells numbered 7,790,000, white blood cells 10,800. The abdomen was distended, tympanic and silent.

Treatment and Result.—To empty the stomach, a Levine tube was passed. Isotonic solution of sodium chloride and 5 per cent glucose were injected by vein. The mass in the left groin was drained under very light anesthesia. It contained foul, gangrenous bowel. The Miller-Abbott tube was passed. In twenty-four hours it was in the midileum. In forty-eight hours it reached the site of obstruction. The patient was given blood plasma, whole blood, salt solution and vitamins by vein, and liquids and soft diet by mouth after the Miller-Abbott tube had reached its destination. Six days after passage of the Miller-

Methods of treating gangrenous bowel in external hernias:

1. Enterostomy done by opening down to gangrenous bowel and inserting catheter into proximal loop. The hernia is not reduced until a later, second operation, when anastomosis is done.
2. Gangrenous bowel in hernia is reduced and exteriorized through an abdominal incision. Anastomosis later.
3. Primary anastomosis done immediately either through femoral canal or through abdominal incision.
4. Questionable bowel is reduced and a short circuiting anastomosis is done.
5. Enterostomy is done through abdominal incision with catheter placed in proximal dilated bowel.
6. (Combination of 2 and 4.) Exteriorization of gangrenous bowel through abdominal incision, with short circuiting anastomosis.
- 6a. Following procedure 6, the blind loops of bowel together with the gangrenous tissue are resected and the ends are turned in.
7. Gangrenous hernia is unreduced, and a short circuiting anastomosis is done through abdominal incision.

fifth day after operation, and the Miller-Abbott tube was removed on the eighth day after the operation. The patient's postoperative course was complicated by a superficial wound infection and by a stomatitis and parotitis. We believe that the stomatitis was caused by a vitamin deficiency, since it promptly receded after administration of nicotinic acid. Both wounds had completely closed by November 17.

CASE 2.—History.—Mrs. E. S., aged 63, was admitted to Robert Long Hospital on Nov. 9, 1942 because of a tender, swollen mass which had appeared in the left groin five days before. Its appearance had been followed by cramping, epigastric pain, nausea and vomiting. No bowel movements had occurred since the day of onset despite enemas and cathartics.

Abbott tube the second operation was done as in case 1. The tube was left in place for six days more. Convalescence was complicated by a mild thrombophlebitis in the left leg. The inguinal incision healed without noteworthy infection. The patient was dismissed on Jan. 17, 1943.

CASE 3.—History.—Mrs. H. T., aged 86, was admitted to St. Vincent's Hospital on March 10, 1945 because of the appearance of a mass in the left groin about three weeks before. This had caused considerable pain but had apparently not caused bowel obstruction until about six days before admission, when the mass suddenly increased in size, and the patient began having cramping, abdominal pain and vomiting. Her condition had become steadily worse.

Examination.—The patient was emaciated and was desperately ill. The abdomen was distended and everywhere tympanic. The pulse rate was 104, the respiratory rate 22, the temperature 99 F. A large, acutely tender mass was present in the left groin. The skin over this was red and edematous.

Treatment and Result.—A preliminary injection of isotonic solution of sodium chloride and glucose was made. Under local anesthesia the hernial sac was incised and drained. It contained gangrenous bowel together with several ounces of soft, yellow fecal material. A Levine tube was passed. The passage of the Miller-Abbott tube was delayed for two days because we thought the patient had a spontaneous fecal fistula. When it became evident that this was not true, the Miller-Abbott tube was passed. This was difficult because of a cardiospasm, which had to be overcome with mercury bougies before the tube would enter the stomach. Once the tube was started, however, its progress was very rapid, and it reached the region of the left femoral ring in about thirty-six hours.

The general treatment of this patient was identical to that described in cases 1 and 2, but at about the time we were considering performing excision of the gangrenous bowel and anastomosis, the patient began to pass flatus and liquid material by rectum. Shortly after this we were able, by the injection of barium, to demonstrate that nature had in some way performed an anastomosis between the obstructed and collapsed portions of the bowel. The patient had had a number of loose bowel movements prior to this examination. We discovered, greatly to our astonishment, that the tube had passed through the newly formed anastomosis and had reached the middle of the transverse colon! The tube was removed, and fifteen days after admission the patient was up and about in her room.

We account for the almost incredible outcome in this case as follows: The small intestine had evidently been incarcerated in the femoral hernia for a period of over three weeks. During this time it is probable that the efferent and afferent portions of the bowel had become adherent where they were in contact. Following this, as the result of the passage of gas and intestinal contents into the incarcerated bowel, this became gangrenous. The gangrenous bowel then became separated from the living bowel, and nature performed an anastomosis between the two ends of living bowel.

Von Mátyás Mátyás³ described a method of treating these cases which consisted in freeing the incarcerated loop of bowel from the femoral ring—usually by division of this ring—followed by the making of a gun barrel enterostomy through the femoral canal. He placed drains around the two barrels of the enterostomy to prevent their retraction. He reports that in 3 cases this procedure was followed by a spontaneous anastomosis between the two ends of bowel. This must have happened in the case under consideration.

COMMENT

All the patients on whom we have used this procedure had femoral hernias. It should be applicable, however, to the treatment of strangulation obstruction in other external hernias. It should be very useful in the management of umbilical hernias containing strangulated pieces of bowel. We have observed 1 case of this condition, untreated, in which nature had performed a gun barrel enterostomy. An abscess which formed in the hernial sac had ruptured spontaneously.

The high death rate for external hernias containing gangrenous bowel is due to errors in treatment which are avoided by the method we have described.

Clinical Notes, Suggestions and New Instruments

PENICILLIN IN THIOURACIL-INDUCED AGRANULOCYTOSIS

HAROLD H. ROTHENDLER, M.D., AND MARTIN G. VORHAUS, M.D.
NEW YORK

Although to date no satisfactory reports of isolated organisms in cases of agranulocytosis have been published, death appears to be due to superimposed infection. This clinical impression has been strengthened by some recent reports of the therapeutic value of penicillin in the treatment of agranulocytosis.¹ Several months ago we ourselves experienced highly satisfactory results with penicillin in treating a case of agranulocytosis of unknown origin, incident to a septic sore throat, after all other known agents such as transfusions, pentnucleotide and liver therapy had failed. The consensus at present indicates that the septic process, which in itself tends to depress granulocytic maturation, is successfully controlled by penicillin.

Our interest in agranulocytosis has been stimulated by our continued study of thiouracil in the treatment of hyperthyroidism.² Though we were fortunate enough to treat our first 60 cases without encountering this serious complication, the expected reaction has been observed by us since publication of our paper. The dramatic response to penicillin of thiouracil-induced agranulocytosis prompts us to note the following case report:

REPORT OF CASE

A woman aged 52 presenting a classic picture of hyperthyroidism, with enlargement of both lower lobes of the thyroid gland and symptoms of five months' duration, was started on a daily dose of 0.6 Gm. of thiouracil. Twelve days later her basal metabolic rate had fallen from plus 85 per cent to plus 18 per cent, her blood pressure had dropped from 170/80 to 140/80, she felt less tired and nervous, and she had gained 6 pounds (2.7 Kg.). Her white blood cell count at that time was 7,750, with a normal differential. Medication was continued unchanged until five days later, when her differential showed 45 neutrophils, with a white blood cell count of 4,000. Thiouracil was stopped immediately. Thirty-six hours later she presented a typical picture of agranulocytosis, with a temperature of 104 F. and a white blood cell count of 2,400, with 2 band cells and 2 segmented neutrophils; this was substantiated by a sternal puncture. On admission to the hospital, penicillin therapy was instituted in doses of 20,000 units administered every three hours. In addition, supportive measures in the form of a transfusion of 500 cc. of whole blood and daily injections of 2 cc. of crude liver were given. Twelve hours later the temperature had dropped to 100 F. and the blood smear showed 8 segmented neutrophils and 12 band cells. Thirty-six hours after the institution of penicillin therapy the white blood cell count had risen to 5,300, with 33 segmented neutrophils and 20 band cells. On the third day the count showed 7,300 white blood cells, with 49 segmented and 7 band cells. The temperature reached normal on the fourth day, and penicillin was discontinued at that time, after the total administration of 560,000 units.

COMMENT

We have presented the report of a case of an agranulocytic reaction due to thiouracil in which early and vigorous penicillin therapy prevented generalized sepsis. We hope that the report of our experience will stimulate workers to the prompt use of this drug in other cases of granulocytic depression.

SATURDAY, NOVEMBER 10, 1945

THE NATIONAL SCIENCE FOUNDATION

For some weeks hearings have been held by the subcommittee of the Committee on Military Affairs of the U. S. Senate on the proposals to create a National Science Foundation, a government agency to be charged with encouragement of scientific research. Several measures have been presented to the Congress to effectuate this objective. Their number and diversity indicate the difficulty of finding the best possible formula. Care is necessary if the objects sought are to be achieved without permitting domination of research by a federal bureaucracy and inhibition of private initiative or the spending of vast funds without adequate return. The work of the Committee on Medical Research and of the Office of Scientific Research and Development during the war proved that funds can be used satisfactorily to encourage research and to coordinate and intensify the speed with which the results of research can be applied. Much was accomplished toward diminishing the lag between the introduction of a new remedy and the determination of its toxicity and its field of usefulness.

Fundamental to the creation of the National Science Foundation is its structural organization. With but few exceptions, leaders of science who appeared in the hearings approved an organization which would be under the control of a directing board which would have as an executive officer a director whom the executive board would nominate to the President. The director would be responsible for administration of affairs of the National Science Foundation, but policies would be determined by the directing board and it would have the responsibility for selecting the universities, hospitals, institutes of research and other agencies to which grants could be made.

Under the directing board would be a number of subsidiary boards dealing with such subjects as the national defense, medicine and the basic sciences. Possibly there might be, in accordance with the recommen-

dation of President Truman, a division for the social sciences, although the point has been made that much research in the field of the social sciences is developed and promoted primarily with a view to securing political and legislative action. The social sciences are themselves so young and their technics at present so experimental and so poorly controlled as to indicate some doubt as to whether or not their development has proceeded sufficiently to warrant incorporation at this time in the proposed agency.

Great care must obviously be exercised as to the technic by which various federal agencies, such as the War, Navy, U. S. Public Health Service, maternal and infant welfare and similar groups are coordinated with the National Science Foundation.

Again the question of patents is introduced by some of the legislative proposals for the creation of the National Science Foundation. A majority of those who participated in the hearings are convinced, that the whole question of patents requires far more study than is now being given to it and that patents might well form the subject of subsequent action, perhaps with the recommendation of the directing board once the agency is established.

Among the best possible activities to be conducted by the proposed National Science Foundation is the creation of fellowships, residencies, traveling scholarships and similar positions to be subsidized with the aid of federal funds. By this technic young men of promise may be given opportunity to show their worth and thus far more competent scientists mobilized in the field of research.

Another function is the encouragement of national and international exchange of scientific and technical information. Unquestionably progress was intensified during the war by the interchange of medical information between the medical research councils of Great Britain, Canada and our own country. In the postwar period a similar organization might involve inclusion of all the nations of the world, perhaps with the aid of a suitable health section developed under the organization of the United Nations.

By the system which prevailed during the war, invaluable time was saved in extending the uses of penicillin and in promoting its manufacture on a large scale and its availability at a small cost. The number of lives thus saved is tremendous, indeed incalculable. Similar investigations in the uses of the sulfonamide drugs, in the development of the uses of blood and the various derivatives of blood and investigations in the treatment of burns, in the control of malaria and many tropical disorders, in diet and in nutrition have brought fruitful results by the utilization of a well coordinated and intensified program of study.

The Board of Trustees of the American Medical Association and a special committee representing the American College of Physicians, the American College of Surgeons and the American Medical Association through the Committee on Postwar Medical Service have recommended enactment of a suitable measure for the creation of a National Science Foundation. As Torald Sollmann has said, "Research is a bird that sings only when it is free. Discovery requires the broadest possible liberty to search in as many places as possible, by as many competent scientists as possible, in any manner and any means that they themselves consider possible." In the structural organization of the proposed National Science Foundation the recommendations of the Magnuson Bill (S. 1285) seem to approach more nearly the type of structure that would achieve the objective sought and conserve the factors of private initiative and liberty that have given the United States a place in the sun where scientific research is concerned.

TOXICITY OF DDT

In order to find a standard cell system for a study of the effects of DDT, Lewis and Richards¹ of the Wistar Institute, University of Pennsylvania, made numerous tests of the possible toxic action of DDT on in vitro tissue cultures. In their preliminary tests a small drop of saturated alcoholic or acetone solution of DDT was allowed to dry on a cover glass. Hanging drop cultures of heart, brain, intestine and spleen from seven to eight day chick embryos or one day rats were set up so as to include the dry DDT. During the seven day observation period the cell growth, migration and mitosis of fibroblasts, entoderm and macrophages were not appreciably different from those in control cultures without DDT. As they moved about in the cultures living fibroblasts often touched or even migrated over DDT crystals without appreciable injury.

This apparent nontoxicity was confirmed with several series of roller tube cultures of heart, liver, kidney, stomach, intestine, skeletal muscle, brain and spinal cord, enough crystals of DDT being added to all but the control tubes to get a saturated solution with many crystals left over. In all cases the outgrowth of fibroblasts, macrophages, entoderm, liver cells, kidney epithelium, nerve fibers and muscle fibers were identical in the DDT and control tubes during the ten to twenty-one day observation period. There was no indication that the DDT had any toxic effects on the cells.

Similar tests were made with a quick killing emulsion consisting of 1 per cent DDT in 9 per cent olive oil, 1 per cent gum arabic and 90 per cent saline solution. Intracardiac injection of this emulsion killed mice within from forty-five minutes to seventy-six hours, control

injections of DDT-free emulsions being nontoxic. Added to roller tube cultures of heart, kidney, stomach, intestine, liver, muscle or nerve fibers, however, the DDT emulsion produced no demonstrable toxic effects.

The seeming paradox of the lethal effects of DDT when administered to intact animals as contrasted with its nontoxicity for individual tissue cells is now under investigation.

MATERNAL AND CHILD WELFARE: THE PEPPER BILL

Senate bill 1318, to make more adequate provision for the health and welfare of mothers and children and for services to crippled children, has not yet reached the stage of hearings. The bill is called the "Maternal and Child Welfare Act of 1945." Grants by the federal government to the states for encouraging preventive medical services and for aiding the crippled and for promoting maternal and infant welfare are now incorporated in our scheme of government. Under the E. M. I. C. program that prevails as a war measure, the chief of the Children's Bureau controls a bureaucracy that functions in a totalitarian manner and without any of the restraints that should be developed in a democratic system of government. The present measure would perpetuate and expand this dangerous invasion of the field of medical care. The director chooses his or her own advisory boards and is not under any compulsion to pay the slightest attention to the recommendations of these boards. In the past such recommendations have been occasionally disregarded. In some instances members have been prevented from giving any publicity to the considerations of the board. Actions have been taken without any public announcement of the proposals to be followed. In many other ways the democratic process has been disregarded.

Without an adequate study as to the needs of the individual states for maternal and infant services and the ability of the states to meet these needs, accurate determination of funds required is not possible. The proposals of the Hill-Burton bill, by contrast, require that each state create a special agency to be concerned with the construction of hospitals, health centers and diagnostic laboratories and that an adequate study of the need be made with the submission and approval of the plan in a public hearing before any grant is made. Under the proposed S. 1318 funds can be spent simply on approval by the chief of the Children's Bureau of any plan that any state submits. In the past, states have been told by the directors of federal bureaus the kind of plans they must submit before they even began thinking of drawing up plans.

Section 103 of the new measure discusses further the approval of state plans. No limitation of any kind is made as to those who would be entitled to governmental or state aid. The bill simply proposes to grant maternal and infant care and care of the crippled to

1. Lewis, W. H., and Richards, A. G., Jr.: *Science* 102: 330 (Sept. 28) 1945.

anybody in the state who applies. In the words of the bill, "services and facilities . . . shall be available to all mothers and children who elect to participate in the benefits of the program." If every mother and child elect to participate, the funds obviously are completely inadequate. The federal government might be asked to provide for the complete cost of maternal care to between 3,000,000 and 4,000,000 mothers annually and for the complete medical care of all children up to the age of 21 years. Assuming a total each year of 4,000,000 cases of maternal care, including children born, stillbirths, abortions and miscarriages, at a minimum cost of \$50 per case, \$200,000,000 a year would be required for that purpose. This would not include the costs of hospitalization. Assuming in the United States 50,000,000 children under 21 years of age, with an average cost per child of \$10 a year for care, the total would be \$500,000,000, making the amount necessary for appropriation for this care \$700,000,000 annually. Adding the costs of hospitalization might involve another 400,000,000 dollars. Unless some restriction is placed on the services to be rendered and the persons to whom they are to be rendered, the government is placed in the position of taking over completely the care of mothers and children and at an annual cost of more than one billion dollars without any special taxation to meet the purpose. This bill would apparently extend the provision of the Social Security Act without increasing the taxation under the Social Security Act for the purposes it intends to serve. And to all of this must be added many millions more as the cost of administration.

By the proposals of part 6 of section 103, as indicated on page 5, maternal and infant care and the care of the child both healthy and crippled would be standardized on a low basis. Such an action would inhibit progress in the care of mothers and children and would, in fact, depreciate the quality of the service rendered. The service given would be service to meet a fixed fee and not the best possible service that should be given according to the needs of the individual patient. Part 8 of this section provides for the introduction of the innumerable forms and reporting systems that bureaucracies require, placing on the medical profession a burden that results in making the form more important than the service rendered.

Part 10 suggests that the same general advisory council shall serve in the state both the maternal and child health and crippled children's programs, which means the establishment of councils that would lack in expert knowledge, since the problem of the crippled child requires a type of expert knowledge quite different from that concerned with the maternal and child health.

Section 104, which concerns payment to states, provides for simple matching appropriations which fail

to take into account that many of our states are quite capable of handling their entire maternal and infant care problem for themselves; other states require federal aid far beyond anything that the state is able to match.

Most pernicious in the entire measure is the provision for federal advisory committees. The chief of the Children's Bureau appoints his own advisory committee, which means that he appoints a committee that will do what he says. If he does not like what the committee does, he may encourage resignation and get another committee. Chiefs of bureaus have not in the past hesitated to enforce secrecy on members of their advisory committees as to publicity given to their considerations. A conference of state health officers is provided for also. The vast majority of the interest of the bill is in medical care; medical care is a physician's problem, not primarily a problem of public health officials. The committee of the Congress which reported out the Hill-Burton bill required that public health centers be not concerned with medical care.

In offering services for crippled children, the measure fails to take into account the varying definitions of crippled children that prevail in individual states. In some states a child with rheumatic fever is considered a crippled child; in other states it is not. The public annually provides through its contribution to the National Foundation for Infantile Paralysis, Inc., some \$15,000,000 to be used in research and locally for the care of the crippled child. Proposals are now being made to collect \$5,000,000 for Sister Kenny's fund. A survey conducted some years ago shows that there are almost a thousand different voluntary organizations for the care of the crippled in the United States, all of them collecting funds from the public for this purpose and all of them having thereby a personal philanthropic interest in the problem. Entrance by the federal government on a large scale such as proposed in this measure for the care of the crippled will depreciate and eliminate the public's interest through these volunteer organizations and thereby probably do more harm than good. Means should be found for coordinating the various activities now existing for the care of the crippled. The state should aid, but the state should not eliminate private philanthropic effort.

For the crippled as for maternal and child care, this law would make the chief of the Children's Bureau a virtual dictator over the care of the crippled in the United States. The federal advisory committees in relation to the care of the crippled are, as with those in maternal and child care, simply tools of the chief of the Children's Bureau.

The Maternal and Child Care Act of 1945 appears to THE JOURNAL to be a hastily conceived, potentially dangerous, piece of legislation. The objectives it seeks to reach are desirable. The proposed measure would not obtain those objectives and would destroy much that has already been done toward their accomplishment.

Current Comment

THE NOBEL PRIZE AWARDS

Sir Alexander Fleming of London and Sir Howard W. Florey and Dr. Ernst B. Chain of Oxford University recently were awarded the 1945 Nobel Prize for physiology and medicine. The 1943 award was made to Drs. Edward A. Doisy, professor of biochemistry at the St. Louis University School of Medicine, and Henrik Dam of Copenhagen, who was in the United States at the time. The 1944 award was presented to Drs. Joseph Erlanger, professor of physiology at Washington University School of Medicine, St. Louis, and Herbert Spencer Gasser, director of the Rockefeller Institute, New York. According to the Stockholm announcement, the 1945 award is made in recognition of the pioneer work of these three investigators in the discovery of penicillin and its healing effects in treating infections. The recipients will share equally in the prize, which amounts to about \$30,000. The history of the discovery of penicillin by Fleming, Florey and Chain and of its application to the treatment of infections has been previously reviewed editorially.¹ Fleming's discovery of penicillin as an antibiotic agent was published in 1929; Florey and Chain demonstrated a method of obtaining penicillin in relatively pure form and first employed this substance clinically during the years 1938 to 1940. Fleming, Florey and Chain are universally recognized as the pioneers in penicillin research, although other workers have contributed greatly to the preparation of penicillin and its clinical use today.

MEDICAL SCHOOL DECELERATION

Elsewhere in this issue is a statement by the Council on Medical Education and Hospitals urging the Army to permit medical school deceleration even though Army Specialized Training students should remain on active duty in the program. Such deceleration would not affect the supply of replacements for medical officers for two years, since the present juniors, completing that year in April 1946 in most schools, could not be available until they have had an additional nine months of accelerated education and an internship of nine months or a year. Insistence on acceleration by the Army would prevent the schools from inaugurating intensive externship "courses" for physician veterans, who will seek such work in increasing numbers. A veterans' externship program can be conducted only in schools whose clinical teaching facilities are freed by the absence of junior and senior externs. The Army has a serious obligation to its own veterans in this matter. Why should not the Army make adjustments similar to those made by the Navy, which is quite willing for medical schools to decelerate at least temporarily, if they wish? Even though certain schools may decide to adopt a modified accelerated program after the current educational emergency presented by the veterans has passed, the need for meeting current obligations is obvious.

VITAMIN K AND INFANT MORTALITY

The value of vitamin K in preventing hemorrhage in the newborn depends on whether a prolongation of coagulation time is an essential feature of the hemorrhagic manifestations. Vitamin K has a definite effect in reducing the coagulation time when prolongation is due to prothrombin deficiency. The prothrombin time is usually prolonged in newborn infants for the greater part of the first week of life. This is the basis for the routine prophylactic use of vitamin K ante partum or neonatally. Confusion exists in the differentiation between true hemorrhagic disease and hemorrhagic manifestations in the newborn, with subsequent variations in the reported incidence and mortality of these conditions. Some investigators have made amazing claims for reduction in the incidence and mortality rate of hemorrhagic disease by routine vitamin K prophylaxis. Sanford and his co-workers¹ in their study of vitamin K were unable to show that hemorrhagic manifestations in the newborn were associated with a prothrombin deficiency; nor were they decreased by administration of vitamin K. Sanford maintained that conditions other than vitamin K deficiency were responsible for the majority of hemorrhagic manifestations in the newborn. Simple evidence of bleeding was not a justification for a diagnosis of true hemorrhagic disease, in which there is a prolongation of prothrombin time and vitamin K is of value. True hemorrhagic disease occurred infrequently, once in 2,500 births in Sanford's series. In order to evaluate claims that vitamin K administered routinely would reduce neonatal mortality rates by decreasing the number of infants who die of hemorrhage, a study was carried out at the Chicago Lying-In Hospital.² Vitamin K was given to all patients delivered for a two year period (1941-1942). Then for the subsequent two year period (1943-1944) medication was not used at all. Examination of the death rates for the two periods showed almost identical rates for the first ten days of life. Of 369 infants who were born dead or who died in the first ten days postnatally, 334 were subjected to postmortem examination. "Each group has approximately the same number of infants with hemorrhagic manifestations, and associated with practically all of these there were abnormalities of labor or delivery which appeared to be definite causative factors." In only 2 infants who were examined post mortem did the possibility of true hemorrhagic disease exist, but in neither was the diagnosis conclusive. Both these infants failed to respond to vitamin K. If these were cases of true hemorrhagic disease, vitamin K failed to cure them; if they were not, then true hemorrhagic disease did not occur in over 13,000 deliveries. Potter concludes that the routine administration of vitamin K does not reduce infant or fetal mortality and that hemorrhagic disease as an entity probably has some other inciting factor than a prolongation of the prothrombin time.

MEDICINE AND THE WAR

ARMY

REGULAR ARMY OFFICERS TO RECEIVE PROFESSIONAL TRAINING

One hundred regular army officers have been assigned to the army general hospitals and medical installations as part of the Army's new plan to give professional training to officers of the Regular Army Medical Department. Under this policy the Regular Army Medical Corps officer will be assured a professional career and will receive graduate training, aid in obtaining board certification for medical specialists from recognized civilian specialty boards and security not usually available in civilian practice. The new program also offers opportunities for Regular Army officers now doing administrative work to understudy doctors who have been active in professional practice during the war. Twenty-one of the one hundred officers have been assigned to specialize in internal medicine and thirty-three in general surgery. The others are assigned in radiology, eye, ear, nose and throat, anesthesiology, neuropsychiatry, urology, pathology, orthopedics, obstetrics and gynecology and public health.

ALLERGY TESTS AT FORT LEWIS

Suitable allergy tests to determine the extent of skin irritation caused by woolen clothing impregnated with insect repellent are to be conducted at Fort Lewis, Washington, under the direction of Capt. Harry Levitt of the Dermatology and Allergy Department at Fort Lee, Virginia.

One hundred and fifty soldiers who have volunteered for the test have been divided into three groups. Fifty will be equipped with untreated woolen uniforms and will act as a control group. Another fifty will wear woolen clothing impregnated with a miticide preparation employing Tween-80 as an emulsifier. The uniforms of the third group will be impregnated with a miticide solution that uses tetrachlorethane as a solvent.

The results of the test will be transmitted to the Preventive Medicine Service of the Surgeon General's Office, Sanitation and Hygiene Division.

STUDY ORGANIZATION AND RESEARCH PROGRAM AT SCHOOL OF AVIATION MEDICINE

The AAF School of Aviation Medicine, Randolph Field, Texas, is to serve as a model for a similar institution to be established in Sweden, according to medical officers from the Swedish Royal Air Forces visiting the United States. The visiting party consisted of Lieut. Col. L. Westering, Deputy Air Surgeon to the Swedish Royal Air Forces, Capt. Kjell Rasmussen, member of the Swedish Air Forces, and Prof. E. Christensen, civilian consultant. After studying the organization and research program of the School of Aviation Medicine they will return to Sweden on completion of a nationwide tour to make recommendations for establishing an aero-medical school in their own country.

TEMPORARY PROMOTIONS

The President recently recommended to the Senate the temporary promotions of the following medical corps officers to the grade of brigadier general:

- Col. Clyde McKay Beck, commanding officer, Ashford General Hospital, White Sulphur Springs, W. Va.
- Col. Sidney L. Chappell, commanding officer, England General Hospital, Atlantic City, N. J.
- Col. Robert M. Hardaway, commanding officer, Bushnell General Hospital, Brigham City, Utah.
- Col. William C. Menninger, director of the Neuropsychiatry Division in the Surgeon General's Office, Washington, D. C.
- Col. Luther R. Moore, surgeon of the Ninth Service Command, Fort Douglas, Utah.
- Col. Edward A. Noyes, surgeon of the Fifth Service Command, Fort Hayes, Ohio.

AWARDED MERITORIOUS SERVICE UNIT PLAQUE

The Medical Detachment of the 1st Infantry Regiment was recently awarded the meritorious service unit plaque for "meritorious service rendered during the Luzon, Philippine Islands, campaign. From Jan. 9, 1945 to April 30, 1945 the Medical Detachment of the 1st Infantry Regiment displayed outstanding devotion to duty in the performance of exceptionally difficult and hazardous assignments. Through the untiring efforts and tenacious determination of the officers and men of the detachment, personnel of the regimental combat team received the highest degree of medical attention, rendered under the most difficult weather and terrain conditions and subject to the hazards of combat throughout the Luzon, Philippine Islands, campaign. Personnel of the medical detachment landed with all assault waves of the Luzon operation and were soon followed by the headquarters personnel, who landed with a nonassault wave. The bombed and shelled civilian population was immediately administered much needed medical aid and, as the combat team progressed toward successive assigned objectives, the ever increasing medical problem of civilian personnel was handled with utmost efficiency and forethought. Throughout the combat assignments medical aid men, surgical technicians, litter bearers and officer personnel advanced with foremost assault elements, constantly displaying aggressive efforts in rescuing wounded personnel from enemy lanes of fire, sheltering them through severe mortar and artillery barrages, administering blood plasma in positions under intense fire, removing the dead from severely contested areas and meeting every demand of our command in rendering prompt and efficient medical aid. Although subject to artillery, mortar and sniper fire, and during constant relocation, rear and forward medical installations were established and operated with such a degree of efficiency and rapidity that administration of medical aid and evacuation to rear echelons were accomplished with a minimum loss of life. . . . The unselfish devotion to duty, advance preparation for expenditure of energy and outstanding initiative of the officers and enlisted personnel of the detachment reflect the highest credit on the military service. The outstanding performance of duty, in addition to exemplary standards of discipline, morale, military courtesy and appearance, merits the fullest credit and is highly commendable."

SWEDISH SURGEON GENERAL VISITS MEDICAL DEPARTMENT

By special invitation of the War Department, Surg. Gen. David Lindsjo and Surg. Comdr. Karl Erick Groth of the Royal Swedish Defense Forces recently visited numerous army installations for the purpose of studying the organization and training methods of the Army Medical Department. Inspection of these installations began with an introductory visit to the Training Division, Office of the Surgeon General, and included Army General Hospitals Walter Reed, Fitzsimons, Kennedy, Halloran, Mason, Thomas M. England and Valley Forge. Their itinerary also included tours of several medical schools, supply depots, research and equipment laboratories and medical induction and separation centers.

AWARDS MADE TO ARMY MEDICAL DEPARTMENT

Of the 1,400,409 decorations given in World War II in recognition of meritorious service and gallantry, 6 per cent were received by Medical Department personnel. These figures are exclusive of the Air Medal and the Purple Heart.

ARMY AWARDS AND COMMENDATIONS

Major John K. Meneely Jr.

The Bronze Star and two oak leaf clusters to the Bronze Star were recently presented to Major John K. Meneely, formerly of New Haven, Conn. The citation accompanying the Bronze Star described his "meritorious service in combat from Feb. 19, 1945 to March 10, 1945 in the Apennine Mountains in Italy. The entry of a regiment of mountain infantry into combat for the first time entailed many problems and difficult situations. During this action in rugged country under the most dangerous conditions Major Meneely, the regimental surgeon, operating under terrific handicaps, planned and directed the efficient and speedy treatment and evacuation of the wounded. Through his tireless efforts and superior personal supervision the regiment's mission was accomplished with the maximum care of personnel, saving many lives and relieving much suffering. This commendable performance earned for him the respect and admiration of all his associates and is deserving of much praise."

The citation accompanying the first oak leaf cluster to the Bronze Star called attention to Major Meneely's "heroic achievement in action of April 29, 1945 near Torbole, Italy. During the fierce fighting on the shores of a large lake a battalion aid station became separated from its collecting point. Major Meneely, aware of the urgent need for reestablishing an area where the wounded might receive maximum care and speedy evacuation, courageously set out in an assault boat during the height of the enemy action to establish an advance station. On arrival at the chosen site he found the terrain unsuitable, so continued onward to a town recently cleared of the enemy. Here he established his collecting point and again exposed himself to deadly artillery fire to reach the regimental aid station, where he informed litter bearers of the newly established collecting area and arranged for proper evacuation from this site. After returning to this forward location he worked tirelessly to insure maximum efficiency in processing the many casualties. His noteworthy accomplishments were essential in the saving of much suffering and life, justly gaining the sincere gratitude and respect of all. The high courage and keen sense of duty displayed by Major Meneely are truly indicative of the highest qualities of the Army Medical Department."

The second oak leaf cluster was awarded "for meritorious service in combat during the period April 14, 1945 to May 2, 1945 in the Apennine Mountains and Po Valley, Italy. As regimental surgeon and commander of the medical detachment during the final offensive in Italy, Major Meneely was faced with the difficult problem of treating and evacuating hundreds of casualties from a rapidly advancing front, which moved from the Apennine Mountains across the Po Valley and into the foothills of the Alps within the space of twenty days. The difficulties of keeping his aid stations moving with the front and operating efficiently to care for the heavy casualties required the finest initiative and skill. Almost every available means of transportation was used to carry the wounded men from the battlefield to the hospital in the rear, including litters, jeeps, ambulances, captured army vehicles and, at one time during the attack along the shores of Lake Garda, amphibious trucks and speedboats. His remarkable organization and execution of this difficult task resulted in the saving of many lives. He constantly worked with the forward aid stations, often under heavy fire, and accomplished his duties at all times, no matter what the difficulties or dangers, with the utmost skill and success. His outstanding achievements have earned Major Meneely the highest commendation and praise." Dr. Meneely graduated from Yale University School of Medicine, New Haven, in 1941 and entered the service Jan. 29, 1942.

Captain Frederick Firestone

The Silver Star and oak leaf cluster to the Silver Star were recently awarded to Capt. Frederick Firestone, formerly of Jamaica, N. Y. As related in the citation accompanying the Silver Star award, "on March 21, 1945, in the vicinity of —, Germany, two men too severely wounded to be moved were left on the field within 30 yards of an enemy machine gun when

their company was forced to withdraw. Captain Firestone, 3d Battalion surgeon, realizing their precarious position, went to their aid. Although he identified himself to the enemy as a medical officer, he was subjected to intense machine gun fire. With utter disregard for his life Captain Firestone, followed by a litter team, crawled 300 yards to the wounded men and, oblivious of the enemy fire, administered plasma, rendered medical aid and supervised their evacuation. His action reflected the highest traditions of the military service."

The following citation accompanied the Oak Leaf Cluster to the Silver Star: "For gallantry in action. On Nov. 20, 1944, on the outskirts of Barr, France, informed that a seriously wounded man could not be evacuated, Captain Firestone, battalion surgeon, secured a plasma set and ran 100 yards through hostile fire to the casualty and administered aid. Later in the day, after several unsuccessful attempts to reach a seriously wounded tank commander lying in a fire swept street, Captain Firestone ran from house to house until directly opposite the casualty. He then crawled into the street and dragged the man into a building, where he administered aid. His actions reflected the highest traditions of the military service." Dr. Firestone graduated from the Faculty of Medicine of the University of Vienna in 1937 and entered the service May 20, 1944.

Major Sigsbee R. Seljeskog

Major Sigsbee R. Seljeskog, formerly of Minneapolis, was recently awarded the Bronze Star "for meritorious service in connection with military operations against the enemy as commanding officer, Hospitalization Unit 1, 13th Field Hospital, from June 8, 1944 to Jan. 4, 1945 in France, Belgium and Germany. Displaying sound judgment and marked ability, Major Seljeskog on landing in France on June 8, 1944 quickly organized and established the first field hospitalization unit to admit casualties sustained in the invasion of the European continent. His initiative and untiring efforts directly contributed to the fulfillment of the extreme medical needs of the amphibious operation and did much to lessen the burden of the overcrowded clearing stations in the beach area. During subsequent operations Major Seljeskog's diligence and industrious attention to duty were instrumental in saving the lives of many troops and in adding to the physical comforts of hundreds of others." Dr. Seljeskog graduated from the University of Minnesota Medical School, Minneapolis, in 1936 and entered the service June 1, 1942.

Captain Albert Kaplan

Capt. Albert Kaplan, formerly of St. Louis, was recently awarded the Bronze Star. "Captain Albert Kaplan," the citation read, "served against the Japanese forces on Luzon, Philippine Islands, from Jan. 11 to June 30, 1945. During this time Captain Kaplan served as company officer and platoon leader in the clearing company of an infantry division. In this capacity Captain Kaplan, through untiring effort and application of superior professional skill, effectively treated hundreds of wounded and sick patients and returned them to duty in a minimum of time. By virtue of a comprehensive knowledge of his assignment, Captain Kaplan personally supervised moving of equipment and establishing model stations in a most rapid and efficient manner. The constant devotion to duty displayed by Captain Kaplan reflects credit on himself and the medical corps and was in keeping with the highest traditions of the military service." Dr. Kaplan graduated from Washington University School of Medicine, St. Louis, in 1936 and entered the service Oct. 9, 1942.

Major John F. Cary

Major John F. Cary, formerly of Sheboygan, Wis., was recently awarded the Bronze Star and a citation for meritorious service in connection with military operations against the enemy from Dec. 24, 1944 to March 25, 1945. The citation states that Major Cary "performed his duties as regimental surgeon in a highly commendable manner. His professional brilliancy, diligence, attention and devotion to duty are in keeping with the finest traditions of the Army Medical Corps." Dr. Cary graduated from Loyola University School of Medicine, Chicago, in 1938 and entered the service March 5, 1941.

Brigadier General Joseph I. Martin

The Distinguished Service Medal was recently awarded to Brig. Gen. Joseph I. Martin, formerly of Washington, D. C., who, according to the citation accompanying the award, "served with distinction as surgeon, Fifth Army, in Italy from December 1944 to May 1945. During the winter of 1944-1945, while the Fifth Army was deployed across the Apennines from a point below Bologna to the Ligurian Sea, he skilfully deployed medical support to meet the rigors of a winter campaign, despite extremely difficult climatic and terrain conditions. As a result of his foresight and wise counsel, disease rates which might otherwise have weakened the Fifth Army before its final attack remained at record low levels. When the victorious April offensives began he devoted himself completely and selflessly to the task of furnishing constant medical service for the sick and wounded. With comparatively few hospitals at his disposal to support an attack of such magnitude, he spent long hours in the field, visiting units under his direction, counseling, supervising and insuring that each casualty received the finest possible medical treatment. He solved the difficult problem of hospitalizing and evacuating thousands of prisoners of war without once jeopardizing the efficient treatment of American and Allied troops. His relations with surgeons of Allied forces under Fifth Army operational control were conducted in the highest spirit of friendly cooperation. His magnificent record of achievement contributed materially to the successful operations of the Fifth Army." General Martin graduated from the Chicago Medical School in 1918 and entered the service July 31, 1918.

Major Walter R. Stager

The Legion of Merit was recently awarded to Major Walter R. Stager, formerly of Dover, Ohio, "for exceptionally meritorious conduct in the performance of outstanding services from March 22, 1943 to June 30, 1945." The official citation stated that "the difficulties and problems involved in maintaining every pilot at his peak of physical and flying efficiency were quickly recognized by Major Stager. His responsibility was great and he executed this responsibility in a superior manner. He proved himself a master of improvisation, and the words 'can't,' 'impossible' and 'unavailable' were not in his vocabulary. In caring for the individuals subject to the bleak weather conditions and monotonous daily life in the Aleutian Islands this officer made his personality and untiring efforts a needed stimulant to the health and happiness of all members of this command. The self sacrifice made, the intense loyalty displayed and the unrelenting devotion to duty shown by Major Stager during his tour of duty have contributed greatly to the activities of the Army Air Forces in this theater." Dr. Stager graduated from Creighton University School of Medicine, Omaha, in 1933 and entered the service Sept. 11, 1942.

Lieutenant Colonel C. B. LaDine

Lieut. Col. C. B. LaDine, formerly of Indianapolis, was recently awarded the Bronze Star for meritorious service in connection with military operations of the 95th General Hospital from May 22, 1944 to Feb. 10, 1945. Colonel LaDine was executive officer and was in charge of the complete organization of the hospital, which was transported to France shortly after 'D' day and served close behind the front lines in the Third Army. Colonel LaDine is now the executive officer of the Thayer General Hospital, Nashville, Tenn. He graduated from Indiana University School of Medicine, Indianapolis, in 1939 and entered the service July 22, 1942.

Lieutenant Colonel Berthel Henning

The Bronze Star was recently awarded to Lieut. Col. Berthel Henning, formerly of San Francisco, "for meritorious service in connection with military operations as commanding officer, 7th Field Hospital, from July 1, 1944 to May 7, 1945. Lieutenant Colonel Henning has maintained the morale and efficiency of the personnel of his unit by his intense zeal, personal example and superior qualities of leadership. Even under the most adverse circumstances with which his personnel had always to contend he kept their operating efficiency at a peak. Although his unit was equipped to handle 400 patients at one time, he

arranged personnel and responsibilities so efficiently that the hospital consistently handled 600 beds, and, at one site, 1,200 beds. Lieutenant Colonel Henning, by superior ability and devotion to duty, was largely responsible for the outstanding accomplishments of the 7th Field Hospital." Dr. Henning graduated from the University of California Medical School, San Francisco, in 1925 and entered the service Feb. 2, 1941.

Captain A. David McKinley

The Soldier's Medal was recently awarded to Capt. A. David McKinley, formerly of Indianapolis, for his heroic action in trying to rescue a wounded pilot from a burning plane on Saipan, January 19. Captain McKinley was the flight surgeon on flight-line duty when the plane, in attempting to take off on a test flight, crashed and burned. The flames soon spread to a cane field and on a large ammunition dump, setting that afire. Quite a large number of officers and men were killed or wounded. Dr. McKinley graduated from Indiana University School of Medicine, Indianapolis, in 1939 and entered the service July 1, 1942.

Major Kenneth B. Babcock

Major Kenneth B. Babcock, formerly of Detroit, was recently awarded the Bronze Star "for meritorious service in support of combat operations in North Africa, Corsica and Italy from June 1, 1943 to May 2, 1945." Major Babcock established and efficiently operated a 100 bed hospital in the Anglo-Egyptian Sudan and later skilfully directed 100 bed hospitals in Libya, Corsica and Italy in climate and terrain varying from the blazing deserts of Africa to the cold, mountainous regions of Italy. Dr. Babcock graduated from the University of Michigan Medical School, Ann Arbor, in 1926 and entered the service Aug. 14, 1942.

Captain Clifton Woolley

The Silver Star was recently awarded to Capt. Clifton Woolley, formerly of Columbiana, Ala. "With utter disregard for his own safety," stated the citation accompanying the award, "Captain Woolley covered 3,000 yards through enemy-held territory to operate on a wounded soldier. . . . The great courage under fire, aggressiveness and devotion to duty displayed by Captain Woolley saved a soldier's life and reflects great credit on himself and the Medical Department of the United States Army." Dr. Woolley graduated from the University of Tennessee College of Medicine, Memphis, in 1939 and entered the service Aug. 20, 1942.

Major John C. Adams

Major John C. Adams, formerly of Portland, Ore., was recently awarded the Bronze Star, having "distinguished himself by meritorious service in connection with military operations from Jan. 21 to May 8, 1945. Major Adams performed his duties in an outstanding manner. Through his surgical skill, sound judgment and devotion to duty he contributed materially to the high standard of medical service rendered by his unit." Dr. Adams graduated from the University of Oregon Medical School, Portland, in 1926 and entered the service 1943.

Lieutenant Colonel Maxwell R. Bernstein

The Bronze Star was recently awarded to Lieut. C. well R. Bernstein, formerly of Pittsburg, Calif. Dr. B has been in China since September 1943 working with American units in the field. He has tended both Chinese American soldiers for the past two years and is now awaiting orders to be returned to the United States. Dr. Bernstein graduated from the University of Illinois College of Medicine Chicago, in 1935 and entered the service April 20, 1941.

Captain John P. Lee

Capt. John P. Lee, formerly of St. Louis, was recently awarded the Bronze Star and a second Presidential Unit citation. He received the Bronze Star "for meritorious achievement in connection with military operations against the enemy on Jolo Islands from April 9 to May 7, 1945." Dr. Lee graduated from Washington University School of Medicine, St. Louis, in 1941 and entered the service Sept. 1, 1942.

MISCELLANEOUS

ITALIAN MEDICAL NUTRITION MISSION

The Italian Medical Nutrition Mission, sponsored jointly by the Unitarian Service Committee and the Congregational Christian Service Committee, is now set up and working in Italy under the United Nations Relief and Rehabilitation Administration.

The purposes of the mission are fourfold: (1) to find out the actual nutritional conditions and needs among the starving people of Italy, (2) to help UNRRA evaluate and improve its feeding program in that country, (3) to make a detailed scientific study of the results of a carefully supervised experimental feeding program for individuals who have suffered prolonged malnutrition, a study that may establish scientific procedures for all further feeding programs, and (4) to help local medical groups in their rehabilitation programs and to encourage their continued scientific study.

The American staff consists of:

Dr. Charles R. Joy, executive director, Unitarian Service Committee.
Robert P. Kellerman, Pacific School of Religion, assistant executive officer.

Dr. Elmer Sevringhaus, University of Wisconsin, co-director and internist.

Dr. Maurice B. Visscher, University of Minnesota, co-director and physiologic nutritionist.

Dr. Ashton C. Cuckler, University of Minnesota, parasitologist.

Ruth M. Flumerfelt, Wisconsin General Hospital, dietitian.

Dr. Frank Gollan, U. S. P. H. S., assistant pediatrician.

Dorothy Hagedorn, R.N., technologist.

Dr. Ancel Keys, University of Minnesota, biochemist and nutritionist.
Marjorie Knowlton, University of Minnesota Medical School, technician.

Dr. Emma Kynos, general medical practitioner, assistant internist.

Dr. Maury Massler, University of Illinois College of Dentistry, dental research, assistant director.

Dr. James Perkins, State of New York Department of Health, epidemiologist.

Dr. Isaac Schour, University of Illinois College of Dentistry, dental research director.

Dr. Lester Sontag, director of Samuel S. Fels Research Institute, pediatrician.

Dr. Ernest L. Stebbins, commissioner of New York City Department of Public Health, epidemiologist.

Northern Italy was found to be in noticeably better condition than southern Italy. In Milan the 1,700 bed hospital was adequately supplied with enough milk, eggs and vegetables, the only dietary shortage being cereals.

A team of Italian doctors and students was trained, and a tuberculosis survey was started on May 21 in Fondi, a community of 17,000. Four thousand persons were examined in twelve days at the clinic. Malaria was almost universal, judging from the history and examination of this 25 per cent sample of the population. The major nutritional problems were rickets, calories and poverty. The findings indicated an overall incidence of tuberculosis below 2 per cent among the 4,000 persons examined. No malaria was found in this community. This team conducted surveys in Sardinia during August and in the southern part of Italy during September.

In a superficial examination of the teeth of returning Italians from Germany, it was found that 62 per cent of these people had less than two carious or missing teeth, although few of them had ever used a tooth brush or had dental care of any sort.

The intensive study program at the clinics of the University of Naples has become increasingly well knit. The entire American staff has now arrived, and daily staff lunches, American and Italian, are a feature that adds greatly to the smooth running of the program and cooperation of the personnel. Miss Flumerfelt, the dietitian, produces an appetizing menu that demonstrates what can be done with UNRRA foods. Bread and macaroni are produced from the specially improved flour that was part of the design of the project.

In the clinics it has been necessary to clarify the differences in diagnosis of nutritional diseases that are due to differences in terminology and to the relative isolation of Italian doctors from research for past years. Finally there came an opportunity to treat a baby who was very nearly dead from prolonged malnutrition plus final dehydration resulting in intoxication. The Italians consented to Dr. Gollan's use of plasma, which had been brought through the courtesy of Sharp and

Dohme, and the results amazed the Italians, thereby opening new paths for study, teaching and prevention of previously unsolved difficulties.

Under the direction and planning of Dr. Sontag the team providing vitally important x-ray films of all children was developed, checking on rickets and on the maturity of the children as shown by bone growth. There are indications of a hitherto unrecognized problem child in Italy in whom stunted growth and development cause a new type of bone disease. A method of approach toward diagnosis and treatment of this condition is being worked out, and a chart system has been organized whereby difficulties will be eliminated in comparing data on these children with those studied in American hospitals. A study of the effects of undernutrition on newborn babies is also under way, suggested by the professor of obstetrics at the university and carried out by joint American and Italian personnel.

One of the great needs of these Italian doctors is for books and journal contacts with the United States, which they are eager to reestablish. An effort is being made to supply them with a nucleus of most needed textbooks, and we are hoping to have journal exchanges set up. One evidence of their being out of touch was an extended debate in staff meeting in which they dilated greatly on the vital merits of mother's milk. It finally became apparent that they were defending their practice of overdiluting cow's milk, since they do not understand the modern methods of safe and adequate babies' formulas. To achieve safety they are sometimes nearly starving the babies. The staff is looking for opportunities to demonstrate to the Italian doctors and through them to the Italian mothers the appropriate methods for modifying cow's milk in such a way that babies will be able to grow normally.

VETERANS

NEW VETERANS ADMINISTRATION
HOSPITALS

As part of the program announced on October 18 by General Omar N. Bradley, Administrator of Veterans' Affairs, for the construction of nineteen new Veterans Administration hospitals with a total of 11,100 beds, thirteen of these hospitals with 9,550 beds are located near medical schools. They are:

Location	Number of Beds	Near
New Haven, Conn.	500	Yale University School of Medicine
Albany, N. Y....	1,000	Albany Medical College

The October 18 list provided also for additions to fifteen existing hospitals and four domiciliary facilities with a total of 4,176 new beds.

Funds for the new hospitals and additions are being requested for the current fiscal year (1946). They are part of the overall 29,100 bed program approved by President Truman on August 4. The remainder of the program, which will be announced later, will be requested for the 1947 fiscal year.

PHYSICIANS SEPARATED FROM SERVICE

ARMY MEDICAL CORPS OFFICERS RECOMMENDED FOR/OR RELIEVED FROM ACTIVE DUTY

Alabama

Bartlett, Haywood S., Capt., 207 Thorn Pl., Montgomery.
Baumhauer, Charles A., Major, Whistler.
Beatty, Thomas D., Capt., Cullman.
Britton, William R., Capt., 120 Bankhead Ave., Montgomery.
England, Francis T., Capt., 50 S. Franklin St., Mobile.
Kahn, Sigmond A., Major, 3005 Canterbury Lane, Birmingham.
Roberts, Edward H., Capt., Choccolocco.
Shamblin, R. D., Capt., 1013 Myrtlewood Dr., Tuscaloosa.
Warren, Claude M. Jr., Capt., Jackson.

Arizona

Fife, Karl L., Capt., Duncan.
Gwinn, Frank W., Major, Box 1511, 300 Gila St., Yuma.
Hurianek, Zdenka A., Capt., 15 E. Monroe St., Phoenix.
Hussong, Ruland W., Capt., 15 E. Monroe, Phoenix.
McNally, Joseph P., Capt., 208 Grove Ave., Prescott.
Oliver, Claude H., Lt. Col., 800 11th St., Douglas.

Arkansas

Armstrong, Howard M., Capt., Baptist State Hosp., Little Rock.
Buckelew, Hollis H., Major, Maunelle Ord. Wks., Little Rock.
Burton, Francis M., Major, 711 Prospect Ave., Hot Springs.
Carrington, Hamilton K., Capt., Magnolia.
Connelly, William B., Capt., Solomon Bldg., Helena.
Donaldson, Joy K., Major, 2107 N. Palm St., Little Rock.
Fulmer, Doyle W., Capt., 819 22 Donagley Bldg., Little Rock.
Gartrell, Luther S. Jr., 1st Lt., Ward.
Grace, Jess K., Lt. Col., Belleville.
Harwell, Carl M., Jr., Lt. Col., Osceola.
Henry, Lewis M., Major, 602 Garrison Ave., Fort Smith.
Hirst, Ottis G., Lt. Col., Prescott.
Hyatt, Cyril L., Capt., 701 Main St., Little Rock.
Imes, Elvin D., Capt., 317 Pecan St., Texarkana.
Jackson, Jabez F., Major, Walnut Ridge.
Kinley, James D., Major, Beebe.
Kirby, Henry V., Capt., 1001 West Nicholson, Harrison.
Madding, G. F., Major, 607 Merchants Bank Bldg., Ft. Smith.
Russell, Allen R., Lt. Col., 521 National Bldg., Pine Bluff.
Sanderlin, Joseph H., Lt. Col., Little Rock.
Sisco, Friedman, Major, Springdale.
Smith, John W., Major, 2115 N. Palm St., Little Rock.
Wickard, Charles P., Capt., 2809 Gaines St., Little Rock.

California

Aldrich, Albert T., Capt., Childrens Hosp., Los Angeles.
Argo, William L., Major, 944 61st St., Oakland.
Armanini, George B., Major, 498 Arques St., Sunnyvale.
Ball, Franklin I., Lt. Col., 6253 Hollywood Blvd., Los Angeles.
Berne, Clarence J., Lt. Col., 2023 Redcliff St., Los Angeles.
Bine, Rene Jr., Capt., 15 26th Ave., San Francisco.
Blasdel, Edward K., Capt., Tulare Co. Hosp., Tulare.
Bruce, Robert A., Major, 1423 Virgil Pl., Los Angeles.
Casey, Earle A., Capt., 917 Bridge Rd., San Leandro.
Churchill, Ambrose S., Capt., 1247 Brunswick, S. Pasadena.
Colm, Roy B., Lt. Col., 106 N. Lucerne Blvd., Los Angeles.
Colby, Elliott G., Col., 2457 Willow St., San Diego.
Cole, Edwin R., Major, 3164 16th St., Sacramento.
Corbin, Damon E., Capt., 4176 Arden Way, San Diego.
Coulter, James D., Major, Western Pacific Hosp., Portola.
Crane, Norman F., Capt., 627 S. Normandie Ave., Los Angeles.
De Fries, William A., Capt., P. O. Box 14, Alamo.
Demakopoulos, Nick, Capt., 320 W. Poplar St., Stockton.
Dryfoos, Herbert L., Major, 167 Beaumont Ave., San Francisco.
Eaker, Alan B., Lt. Col., Santa Fe & Eight St., Carmel.
Escamilla, Roberto F., Major, 3325 Jackson St., San Francisco.
Evans, W. L., Major, 3044, The Mall, Wyvernwd, Los Angeles.

Council on Medical Education and Hospitals

MEDICAL SCHOOL DECELERATION AND THE PHYSICIAN VETERAN

A Statement from the Council on Medical Education and Hospitals

The medical schools of the country anticipated the increased wartime need for physicians and inaugurated the accelerated program in medical education. Enrolments were increased. The program has been maintained successfully despite great losses in faculty. The medical schools submitted to the inadequate premedical programs of the armed forces and to the educationally undesirable 9-9-9 program believed to be necessary in the emergency. The medical schools have cooperated willingly and vigorously in every effort to win the war.

Now after four years, with the war won, there are responsibilities which should take precedence over the accelerated training of medical officers. These are (1) provisions for the education of physician veterans and (2) restoration of a sound educational program. Most if not all schools indicated at the recent Pittsburgh meetings of the Association of American Medical Colleges that they desire to return to the prewar program at once: to commence their 1946-1947 session in the fall, even though the 1945-1946 academic year ends in April, as is the case in most schools. A number of institutions propose to employ three to six months of this period for the education of physician veterans, particularly along externship lines. Such schools point out that the absence of juniors and seniors from the school will free the clinical facilities for the veteran physician programs.

Since large numbers of physician veterans are seeking such work, and many more will apply by spring, the schools should be permitted to develop such plans. The Navy does not object. The Army hopes to continue the Army Specialized Training Program into 1947 for all men now in the program; it is unwilling that schools under contract should decelerate. In effect, this is an arbitrary compulsion on the schools and on the vast majority of medical students, since only about 20 to 25 per cent of medical students in June 1946 will remain in the A. S. T. P. The medical schools have repeatedly adjusted to the desires of the Army. Cannot the Army now adjust to the new responsibilities of the schools, and more particularly to the needs of physician veterans seeking further education? Such needs are more compelling than the probable need for replacements two years hence. The plan outlined would not affect the supply of replacements for medical officers before that time.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Federal Program for Hospital Construction

The Senate Committee on Education and Labor has favorably reported a revised version of the Hill-Burton hospital construction bill, S. 191. As reported, the bill would provide for a five year hospital construction program and authorize annual appropriations of \$75,000,000 for each of the fiscal years 1947-1951 inclusive plus unappropriated and unexpended balances. It eliminates the \$5,000,000 authorization that appeared in the original bill for state administrative expenses in carrying out state plans. A new provision in the reported bill denies to any federal officer or employee the right to exercise any supervision or control over the administration, personnel, maintenance or operation of any hospital with respect to which any funds are expended under the federal measure.

Veterans Administration

The House Committee on World War Veterans' Legislation has been holding hearings on a bill introduced, by request, by Representative Rankin, Mississippi, to establish a Department of Medicine and Surgery in the Veterans Administration, H. R. 4225. This bill, it is understood, was introduced at the request of the Veterans Administration and proposes a reorganization of the medical department in an effort to make available a better quality of medical care to veterans. Among other things, it would authorize the Administrator of Veterans' Affairs, on the recommendation of the Surgeon General, to employ physicians on a full time, part time or fee basis at such rates of pay as may be prescribed. This employment would be in addition to the commissioned or noncommissioned personnel of the proposed corps.

Representative Dirksen, Illinois, has introduced H. R. 4363, a bill providing special facilities for handicapped veterans. It would authorize the Administrator of Veterans' Affairs to establish not to exceed ten special schools to be known as United States veterans' universities to enable veterans handicapped by physical disabilities effectively to take advantage of the educational privileges extended by the G. I. Bill of Rights.

Discharge of Physicians

A bill introduced by Representative Traynor, Delaware, H. R. 4475, would provide for the release from active service of every commissioned officer serving in the Medical Corps, Dental Corps or Veterinary Corps of the Army or the Medical Corps of the Navy or the Navy Dental Corps who (a) has attained the age of 36 years and whose active service has been of a duration of two years or more since Sept. 16, 1940, (b) has performed active service outside the continental limits of the United States or in Alaska for one year or more since Sept. 16, 1940 or (c) during World War II was for thirty days or more in the hands of the enemy as a prisoner of war.

Control of Hay Fever

Representative Lane, Massachusetts, has introduced H. R. 4279, proposing an appropriation of \$50,000 for expenditure, under the direction of the Surgeon General of the United States Public Health Service, for research with respect to the cause and cure of hay fever.

Coming Medical Meetings

American Medical Association—House of Delegates, Chicago, Dec. 3-6. Dr. Olin West, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Allergy, Chicago, Dec. 10-11. Dr. Karl D. Figley, 316 Michigan St., Toledo 2, Ohio, Secretary.

American Association on Mental Deficiency, Cleveland, Nov. 28-Dec. 1. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American Ophthalmological Society, Hot Springs, Va., Nov. 12-14. Dr. Walter S. Atkinson, 129 Clinton St., Watertown, N. Y., Secretary.

American Society of Anesthetists, New York, Dec. 12-13. Dr. McKinnie L. Phelps, 745 Fifth Ave., New York 22, Secretary.

American Society of Tropical Medicine, Cincinnati, Nov. 12-15. Dr. Joseph S. D'Antoni, Tulane Ave., New Orleans 13, Secretary.

International College of Surgeons, U. S. Chapter, Washington, D. C., Dec. 7-8. Dr. Louis J. Garieny, 16401 Grand River Avenue, Detroit, Secretary.

North Pacific Pediatric Society, Portland, Ore., Dec. 1. Dr. Aldis B. Johnson, Cobb Bldg., Seattle 1, Washington, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Nov. 26-29. Dr. Elmer R. Musick, 512 Medical Arts Bldg., Oklahoma City, Secretary.

Puerto Rico, Medical Association of, San Juan, Dec. 14-16. Dr. Rafael A. Vilar, P. O. Box 3866, Santurce, Secretary.

Southern Medical Association, Cincinnati, Nov. 12-15. Mr. C. P. Loranz, Empire Bldg., Birmingham 3, Alabama, Secretary.

Southern Surgical Association, Hot Springs, Va., Dec. 4-6. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

COLORADO

State Election and Meeting.—Dr. Archie C. Sudan, Krennmling, was chosen president-elect of the Colorado State Medical Society at its annual meeting in Denver, September 21. Dr. George A. Unfug, Pueblo, was inducted into the presidency. Dr. George H. Gillen, Denver, was elected vice president, and Dr. Bradford J. Murphey, Denver, was chosen secretary for a three year term. Dr. William T. H. Baker, Pueblo, was named delegate to the American Medical Association for a two year term. Among the speakers at the recent session were:

Dr. Lewis G. Allen, Kansas City, Value of the Scout Film of the Abdomen.

Dr. Theodore E. Beyer, Denver, Sialography.

Col. John Murray, M. C., Fort Logan, Management of Anxiety State of Returnees.

Allen E. Walker, P. A., Surg. (R) U. S. Public Health Service, Denver, Rapid Treatment Center Method of Handling Syphilis.

Dr. Edward R. Mudge and Marion Rymer, both of Denver, Belle Bonfils Blood Bank.

The program also included symposiums on hepatitis, upper respiratory infections and care of amputations following operation. There was also a clinic on unusual skin cases presented by Dr. Arthur R. Woodburne, Grand Rapids, Mich. Dr. John R. Evans, Denver, was toastmaster at the banquet, at which the guest speaker was Robert L. Stearns, LL.D., Boulder, on "Postwar Science in the Light of Our War Experiences."

ILLINOIS

Oldest Practicing Physician in State.—Dr. Edmund B. Montgomery, Quincy, is said to have practiced medicine in Illinois longer than any other physician, according to recent newspaper reports. In a statement to the press Dr. Harold Swanberg, Quincy, said that Dr. Montgomery has been in active practice for sixty-seven years, that he is the oldest member of the Adams County Medical Society, joining it in 1879, and that he has been a member of the Illinois State Medical Society longer than any other physician in the state. Dr. Montgomery was born in St. Louis May 11, 1858 and graduated at Jefferson Medical College of Philadelphia in 1878.

Chicago

Leon Jacobson Named Associate Dean.—Dr. Leon O. Jacobson, assistant professor of medicine at the University of Chicago School of Medicine, has been appointed associate dean of the university's Division of Biological Sciences. Dr. Jacobson, who graduated at the medical school in 1939, has been a member of the university's staff since 1941.

George A. Wiltrakis Named to Mental Hygiene Post.—Lieut. Col. George A. Wiltrakis, M. C., on October 15 was appointed by the governor, Dwight H. Green, as deputy director of the mental hygiene service of the Illinois Department of Public Welfare. Dr. Wiltrakis, who graduated at Loyola University School of Medicine, Chicago, in 1929, has been on terminal leave from the Army since September 29, according to the *Chicago Sun*. He succeeds Dr. Conrad S. Sommer, Chicago, who went to St. Louis (THE JOURNAL, September 15, p. 221).

Meeting of Bacteriologists.—The Society of Illinois Bacteriologists will hold its fall meeting November 16 at Huyler's Restaurant, 310 South Michigan Avenue. The speakers will include:

Henry J. Gorecki, Ph.D., Production and Dehydration of Bakers' Yeast.
Howard J. Shaughnessy, Ph.D.; Albert Miltzer, Ph.D.; John L. Neal, Ph.D., and Dr. Sidney O. Levinson, Studies on Irradiated Polyalcohol Bacterial Dysentery Vaccine.

Dr. Preston E. Harrison, Effect of Chemotherapy on the Development of Immunity.

Joseph Zichis, Ph.D., Catherine E. Lemke, M.S., and Dr. Shaughnessy, Occurrence of Psittacosis-like Viruses in Chicago Pigeons.

Dr. Guy P. Youmans, Culture Cycle of Virulent Human Type Tubercle Bacilli.

Lying-In Hospital Observes Fiftieth Anniversary.—A program of clinics and papers formed the official observance of the fiftieth anniversary of the Chicago Lying-In Hospital and Dispensary of the University of Chicago October 29.

Morning clinics were conducted by Dr. William J. Dieckmann, chief of service at Chicago Lying-In clinics, by Dr. Fred L. Adair, professor emeritus of the university and former chief of service, and four members of the Lying-In staff: Dr. Morris E. Davis, Dr. Henry C. Hesselstine, Dr. Edith L. Potter and Dr. James R. Willson. Among speakers on an afternoon program were:

Dr. Frederick C. Irving, Boston, A Blood Bank for a Lying-In Hospital.

Dr. Henricus J. Stander, New York, Teaching of Obstetrics and Gynecology.

Dr. Edwin C. Hamblen, Durham, N. C., Some Contributions of Endocrinology to Obstetrics and Gynecology.

Dr. Norman F. Miller, Ann Arbor, Mich., Hysterectomy—Therapeutic Necessity or Surgical Racket?

At dinner in the evening a check for more than \$300,000 for research in the fields of eclampsia and puerperal fever was presented to Robert M. Hutelins, chancellor of the University of Chicago, by the board or directors of the hospital, where the research will be carried out.

Solomon Memorial Research Foundation.—The Dr. Jerome D. Solomon Memorial Research Foundation has recently been created to "conduct scientific investigation in the field of medicine and surgery for the relief of human suffering, irrespective of race, color or creed." The foundation is named for Captain Solomon, who died of scrub typhus at Cape Sansapor, New Guinea, September 16, aged 28. Dr. Solomon had graduated at the University of Illinois College of Medicine in 1941, becoming in the same year a lieutenant in the medical corps of the Army of the United States. He entered active duty in 1942. Joseph D. Solomon, father of Dr. Solomon, is honorary president of the new foundation. Other officers include M. Z. Holland, president; N. R. Levin, vice president; Dr. Joseph L. Wilkey, Chicago, vice president; Irv Kupcinet, Chicago Daily Times columnist, secretary; Zena L. Graham, assistant secretary, and William Lakritz, treasurer. Members of a medical advisory board are Drs. Morris Fishbein, chairman, Ludvig Hektoen, Andrew C. Ivy, Raymond W. McNealy, Karl A. Meyer and Samuel J. Hoffman. Research will be carried out at the Hektoen Institute, which is affiliated with the foundation. Fellowships will be awarded in projects recommended by the medical advisory committee. The foundation is now conducting a membership drive at \$10 a person, and voluntary contributions are requested.

Conference on Tuberculosis.—"Control of Tuberculosis in the Metropolitan Area" will be the theme of a conference at the red lacquer room, Palmer House, November 13-14. The conference is sponsored by the Institute of Medicine of Chicago in cooperation with the Chicago Medical Society, the Tuberculosis Institute of Chicago and Cook County, the Council on Social Agencies of Chicago, and the Chicago Tuberculosis Society. Among the speakers will be:

Dr. Daniel J. Glomset, Des Moines, History and Development of Tuberculosis.

Dr. Herman E. Hilleboe, Washington, D. C., Case Finding.

Col. Midian O. Bousfield, M. C., Fort Huachuca, Arizona, Tuberculosis in Negroes.

Dr. Harry J. Corper, Denver, Fundamental Information on the Mechanism of Specific Tuberculosis Immunity.

Dr. Francis M. Pottenger Jr., Monrovia, Calif., Dietary Aspects of Tuberculosis.

Dr. William F. Petersen, Chicago, Season and Tuberculosis.

Dr. Bruce H. Douglas, Detroit, Sanatorium Facilities.

Dr. Robert G. Bloch, Chicago, The Role of General Hospitals and Clinics and the Private Physician.

Bleeker Marquette, Cincinnati, Housing of Tuberculosis and Health.

Metta Bean, Milwaukee, The Tuberculous Patient.

Homer J. Buckley, Chicago, Education of Public Authorities and the Lait in Tuberculosis.

Dr. Arthur H. Parmelee, Oak Park, Ill., Tuberculosis in Children.

Dr. Jay A. Myers, Minneapolis, Tuberculosis as a School Problem.

Mabel E. Ruger, Michigan, The Practical Application of Instructional Methods in Schools.

Dr. Maxim Pollak, Peoria, Ill., Tuberculosis in Industry from the Viewpoint of the Physician in Industry.

Dr. Leo Price, New York, The Problem of Tuberculosis Industry from the Viewpoint of Labor.

L. E. Roark, Management's Interest in Tuberculosis Control in Industry.

Dr. Jerome R. Head, Chicago, Principles and Organization of Treatment.

Dr. Camillo E. Volini, Chicago, Pneumothorax Therapy, Including Ambulatory Pneumothorax Treatment.

Dr. William E. Adams, Chicago, Surgical Treatment of Tuberculosis.

Dr. Paul T. Chapman, Detroit, Follow-Up Problems, Including the Chronic Open Case.

Dr. Harry A. Pattison, Livingston, N. Y., Rehabilitation.

The program will also include a series of panel discussions on public financing of tuberculosis programs, the problem of the tuberculous war veteran, immunization with the bacillus Calmette-Guérin and the education of medical students and physicians in tuberculosis.

KENTUCKY

John Phair Named Health Officer of Louisville.—Dr. John J. Phair, associate professor of epidemiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, has been appointed professor and head of the department of public health and bacteriology at the University of Louisville School of Medicine and health director of Louisville and Jefferson County. He succeeds Dr. Hugh R. Leavell, Louisville, who has been given a position with the Rockefeller Foundation as assistant director for the medical sciences (*THE JOURNAL*, August 18, p. 1179). Dr. Phair is now in Europe as adviser to Major Gen. N. C. Stayer, director of public health, welfare and education of the United States Control Council in Germany and will assume his new work the first of the year. He graduated at the University of Cincinnati College of Medicine in 1929. Dr. Gracie R. Rowntree, Louisville, has been acting director of the city and county health unit since Dr. Leavell left Louisville last November.

LOUISIANA

Research on Enzymes.—The Smith, Kline and French Company has made a grant of \$5,000 to the Alton Ochsner Medical Foundation for research in chemistry, according to Dr. Thomas P. Findley Jr., New Orleans, the research director of the foundation. This fund will be used to continue the work on enzymes which is being done by Dr. Otto Schales, New Orleans, director of the chemical research laboratory.

MISSOURI

Personal.—Dr. Curtis H. Lohr, who recently returned to his activities as superintendent and medical director of the St. Louis County Hospital, Clayton (*THE JOURNAL*, August 18, p. 1179), is serving temporarily as health officer of Clayton. —Dr. Raymond A. Ritter has been named chairman of the Cape Girardeau board of health.

Industrial Survey in Franklin County.—The Missouri state industrial hygiene service has recently inaugurated a series of surveys, the first of which is being conducted in Franklin County. The object of the new survey is to determine to what extent a comparatively rural county such as Franklin can support an industrial medical program. The Franklin survey is being carried out by the state industrial hygiene service in cooperation with the Franklin County Medical Society. Dr. A. Link Koven, Jefferson City, is chief of the industrial hygiene service and W. Scott Johnson is chief public health engineer. Dr. Koven recently gave a talk before the Franklin County Medical Society on "Industrial Medicine and Its Potential Importance to Franklin County."

NEW YORK

Ninety Years of Age.—Dr. Charles E. Lane, Poughkeepsie, observed his ninetieth birthday August 16. The Poughkeepsie *New Yorker* reported that Dr. Lane is still taking care of office calls.

Black Market Charged in Surgery Dressings.—John F. X. McGohy, United States attorney, announced yesterday the filing of a nineteen count criminal information charging that Irving Tow, 405 East Fifty-Fourth Street, former general and executive manager of the American White Cross Laboratories, Inc., 52 Webster Avenue, New Rochelle, diverted 627,281 yards of finished cotton piece goods that had been acquired for military surgical requirements. According to the *New York Times* the information alleges that the merchandise was sold by Tow between August 1943 and May 1944 to manufacturers of women's and children's garments for \$61,385, or \$10,790 above the ceiling prices.

Commonwealth Fund to Finance Study on Hospital Care.—The Commonwealth Fund has given fifteen hospitals in five counties of New York \$275,000 a year for five years to finance an educational and building program of outlying hospitals, according to the *Rochester Chronicle*, October 14. Formation of a regional council with the Rochester Hospital Council as a nucleus will be the first step in setting in motion the plan, which is expected to become operative about January 1. The hospitals that applied to the fund for the approval of this region were Bath Memorial, Bath; Bethesda and St. James Mercy, Hornell; Brockport Central, Brockport; Dansville General, Dansville; Clifton Springs Sanitarium, Clifton Springs; Frederick Ferris Thompson, Canandaigua; Geneva General, Geneva; Soldiers and Sailors Memorial, Penn Yan, and Genesee, Highland, Park Avenue, Rochester Gen-

eral, St. Mary's and Strong Memorial, Rochester. Of the total amount of the award, \$75,000 yearly is to be used for administration and educational programs and \$200,000 as grants-in-aid to member hospitals in smaller communities for building programs and purchase of equipment. The educational program will be perhaps the primary function of the new council and will be on a postgraduate level. It will include organization and administration of a continuous postgraduate program for physicians and will include clinical conferences, short refresher courses and one to three year residencies and fellowships, depending on demands from the standpoint of content and time. The plan provides for a possible rotation of interns and residents among the hospitals throughout the region, a refresher course for graduate nurses, postgraduate nurse training in war management, operating room and delivery room courses, institutes and consultation and exchange opportunities for laboratory technicians, x-ray technicians, dietitians, medical record librarians, admitting officers and development of opportunities for more extensive affiliation in undergraduate nursing. Also provided is extension of consultation services in such fields as x-ray, pathology and anesthesia and for hospital administrative and departmental problems. The program also calls for meetings and regional institutes for nonprofessional as well as professional hospital personnel. The Rochester Hospital Council began as an administrators' conference body shortly after World War I and continued as such until its incorporation in December 1939.

New York City

Dental School Loses Rating on Merger with Medical School.—The council on dental education of the American Dental Association is reported to have withdrawn its rating of the School of Dental and Oral Surgery of Columbia University as a result of the recent merger of the institution's medical and dentistry faculties (*THE JOURNAL*, March 10, p. 606).

Institute Named for Caroline Zachry.—The Institute of Human Development will be renamed in memory of the late Caroline B. Zachry, Ph.D., who at the time of her death in February was director of the bureau of child guidance of the city board of education. The institute was established by Dr. Zachry in 1939 to bring together teachers, doctors, nurses, social workers and other professional persons, to help them to learn from one another and to work together for children. It has carried on research, supervised field studies, presented lecture courses and held workshops and seminars for advanced students in education, medicine and social work. Dr. Zachry resigned as head of the institute in 1942 to direct the city bureau. It is also planned to publish the proceedings of a one day conference on adolescents this fall as a memorial to Dr. Zachry.

Ernest Stebbins Goes to Johns Hopkins.—Dr. Ernest L. Stebbins, commissioner of health since 1942, has been appointed professor of public health administration and assistant director of Johns Hopkins University School of Hygiene and Public Health, Baltimore, *Science* reports. Dr. Stebbins graduated at Rush Medical College, Chicago, in 1929 and received his M.P.H. degree at Johns Hopkins in 1932. In 1931 he was epidemiologist with the Virginia State Department of Health and health officer in Henrico County from 1932 to 1934, when he went to the New York State Department of Health as epidemiologist. In 1937, after a period as district state health officer, he became director of the division of communicable diseases of the state health department and subsequently assistant commissioner of health. From 1940 to 1942 he was professor of epidemiology of the Columbia University College of Physicians and Surgeons.

NORTH CAROLINA

Grants for Research.—The medical relations division of Camel Cigarettes has given the Bowman Gray School of Medicine, Winston-Salem, an additional grant of \$6,000 to support research on tobacco by William A. Wolff, Ph.D., associate professor of pathology. This grant brings to a total \$22,651 awarded for the support of this work. A grant of \$2,500 has been received from the John and Mary R. Markle Foundation to aid the research conducted by Dr. David Cayer, Durham, assistant professor of medicine, on the study of nutrition. Dr. Cayer formerly was associated with Dr. Julian M. Ruffin of the Duke University School of Medicine, Durham, in the study of vitamin levels in various deficiency states. Dr. Cayer will

continue study along the same lines under this grant. A grant has been received from the American Foundation for Tropical Medicine to aid in the publication of studies done by the department of medicine on lepromin skin reactions.

NORTH DAKOTA

Appointments to Health Department.—Three staff appointments to the state department of health have been made by Dr. George F. Campana, Bismarck, state health officer. Miss Bernardine Cervinski will be director of health education, Mr. Fred J. Baker has been assigned as chemist in the public health laboratory at Bismarck and Mr. Richard M. Ludemann will be lay venereal disease investigator for the division of preventable diseases.

New District Health Unit.—The Southwestern District Health Unit, comprising the counties of Golden Valley, Billings, Slope, Bowman, Hettinger and Adams, has been created with headquarters in New England with Dr. Mary E. W. Soules, Dickinson, as health officer. According to an announcement from Dr. George F. Campana, Bismarck, state health officer, the district board of health includes Mr. M. S. Byrne, Bowman, president; Mrs. Clara Brown, Amidon; L. S. Riley, dentist, New England; Mr. Lewis Odland, Beach; Mr. A. E. Boicourt, Medora, and Dr. John L. Dach, Hettinger.

PENNSYLVANIA

Philadelphia

Pigeons Declared "Prejudicial to Public Health."—The Philadelphia Department of Health has adopted a resolution declaring the city's public pigeons to be "prejudicial to public health," and the public health committee of the city council has amended an ordinance which will permit city officials to trap and kill the birds. From 35 to 48 per cent of a group of pigeons studied for disease recently were found infected with ornithosis. In a statement to the press, Dr. Rufus S. Reeves, director of public health, stated that the pigeons would be killed in the truck borne gas chambers of the Pennsylvania Society for Prevention of Cruelty to Animals.

Proposed Diabetic Survey.—A cooperative project will be conducted in Philadelphia to x-ray the chests of persons in the city having diabetes. The x-ray unit will be located first, beginning in late November, at the University of Pennsylvania Hospital, where there are 500 diabetic patients attending the clinic. It will then move to the Philadelphia General Hospital, where there are 1,000 diabetic patients attending the clinic. The cost of the survey will be borne by the Philadelphia Tuberculosis and Health Association. The appointment of necessary committees will be under the guidance of the Philadelphia County medical committees on diabetes and tuberculosis together with the x-ray survey committee of the Philadelphia Tuberculosis and Health Association. At the meeting September 24 at the Philadelphia County Medical Society, physicians interested in diabetes and tuberculosis discussed the various aspects of the survey, bringing out that it would be invaluable in shedding light on certain concepts long held regarding the response of diabetic patients to tuberculosis. It was further brought out that a mass survey might confirm or refute the concepts that hilar and basal sites are more frequently involved in tuberculous diabetic patients. The recording of simple data relevant to nutritional status might illumine the question as to whether or not nutritional status is one of the major factors in the increased susceptibility of diabetic patients to tuberculosis. It is proposed to divide the city into districts, installing a mobile x-ray unit in suitably located central hospitals for the x-ray examination of the diabetic patients in the vicinity and of nondiabetic outpatient controls.

TEXAS

Graduate Program on Psychiatry.—Dr. Stephen Weisz, Galveston, associate professor of neuropsychiatry, University of Texas Medical Branch, Galveston, is conducting a post-graduate program on psychiatry at the San Antonio State Hospital, San Antonio, under the auspices of the State Board of Control, the Hogg Foundation for mental hygiene and the medical school.

Beryl Burns Named Medical Director of Sealy Hospital.—Dr. Beryl I. Burns, who recently resigned as dean of the Louisiana State University School of Medicine, New Orleans, has been appointed medical director of the John Sealy Hospital and affiliated hospitals of the University of Texas Medical Branch, Galveston, effective in December. He will

have charge of professional activities and will be assisted by Mr. William O. Bohman, superintendent of the hospital, in respect to administrative details. He will also act as consultant in the erection of a new general hospital building as provided by grants from the Sealy and Smith Foundation.

UTAH

New Acting Dean.—Dr. Hyrum L. Marshall, Salt Lake City, professor and head of the department of public health and preventive medicine, has been named acting dean of the University of Utah School of Medicine, Salt Lake City. The administrative committee which formerly acted in the deanship capacity has, at its request, been dissolved (THE JOURNAL, March 17, p. 665). On recommendation of the executive committee of the medical school and with the approval of the board of regents of the University of Utah, a separate department of anesthesiology has been established in the school of medicine. Dr. Scott M. Smith, St. Louis, has been named assistant clinical professor of anesthesiology and acting head of the department.

University News.—The Givaudan-Delawanna Corporation has granted to Dr. Philip B. Price, professor of surgery, University of Utah School of Medicine, Salt Lake City, \$5,250 for the investigation of skin disinfection. The senior class has initiated a successful campaign to secure funds to add to the journal subscription of the medical school library. The members have assessed themselves \$20 each for this purpose and from this source and others interested in the medical school have now collected more than \$3,500. Dr. Randolph T. Shields, formerly surgery resident at the University of Pennsylvania School of Medicine, Philadelphia, and more recently major in the U. S. Army Medical Corps in the China-Burma-India theater, has been appointed instructor in surgery. The medical students on active duty with the armed forces, assigned to this institution for the study of medicine, have voluntarily initiated a payroll contribution plan whereby each student in the military service donates \$2 a month toward a student loan fund to be used to help finance medical education of needy civilian students. At the present time this fund totals over \$3,500.

WEST VIRGINIA

Charles Lively Named Permanent Secretary of State Association.—The council of the West Virginia State Medical Association October 14 elected Charles Lively, Charleston, as permanent executive secretary of the state medical association to succeed Major Joe W. Savage, who has accepted a position with the National Foundation for Infantile Paralysis, New York (THE JOURNAL, October 16, p. 472). Mr. Lively has been acting secretary of the state medical association since May 1942. The council also voted for a three day annual meeting at Huntington, May 13-15, 1946.

Review of Cancer Referrals.—In the fourteen months during which the state division of cancer control has been functioning, 703 referrals have been reviewed, a number far greater than was anticipated at the time the program was inaugurated. Of the total number of cases referred, 88.1 per cent have proved to be malignant. The amount expended for treatment exceeds \$46,000. Because of the unexpectedly high number of referrals of needy cancer patients, the cancer division has restated and clarified its policies and procedures concerning the extent of care that can be provided. As a result of suggestions and recommendations made by the cancer committee of the West Virginia State Medical Association, the following policies have been adopted:

Financial assistance can be extended only to those needy cancer patients who present a good prognosis. The division is not to authorize prolonged hospitalization to the incurable case, thereby jeopardizing the treatment of those patients who have a good possibility of cure. The division cannot assume any financial obligation for treatment or hospitalization of a case until the application has been reviewed and the necessary authorizations issued. Services and treatment can be given only at approved treatment centers and tumor clinics.

Bruce H. Pollock Named Deputy State Health Commissioner.—Dr. Bruce H. Pollock, formerly of Huntington, has been appointed deputy state health commissioner, succeeding Dr. Albert L. Chapman, Charleston, who has been serving as acting deputy on loan from the U. S. Public Health Service since 1944. Dr. Pollock was serving as director of the bureau of county health work in the state health department when he entered the Navy in 1941 with the rank of lieutenant. He was later promoted to the rank of lieutenant commander. He was first assigned to the Norfolk Navy Yard and then served as medical and sanitary officer with a Marine air group in the South Pacific. After his return to this country he served as flight surgeon at the office of Naval Officer

Procurement, Philadelphia, and at the Naval Air Technical Training Center at Memphis, Tenn. In 1936 he was connected with the West Virginia Training Center at Beckley and was responsible for the organization of Clay, Braxton, Webster and Nicholas counties into the first district health unit in the state.

GENERAL

Braille Society Makes First Public Appeal.—The Braille Institute of America recently launched the first special appeal for funds ever made to the public in its twenty-five years' existence. An expansion program is necessary to meet the needs of returning blind service men.

Poliomyelitis Commission Goes to Brussels.—A medical commission left New York October 24 for Brussels under the auspices of the National Foundation of Infantile Paralysis to help in the epidemic of poliomyelitis in Brussels, Belgium. Members of the commission include Dr. Rustin McIntosh, director of pediatrics at Babies Hospital, New York; Dr. Charles E. Irwin, chief surgeon of the Georgia Warm Springs Foundation, and Miss Alice Lou Plastring, chief physical therapist at Warm Springs.

Resolution Seeks Assurance of Freedom in Animal Experimentation.—The recently organized Southwestern Section of the Society for Experimental Biology and Medicine has adopted a resolution announcing its plan to request state and national legislative bodies, through their appropriate committees, to assure the freedom of responsible scientific research in biology and medicine involving animal experiments, provided always that the animals in question are properly cared for and not required to suffer pain. The resolution, which was carried unanimously by members of the Southwestern Section, emphasized that experimentation with animals under satisfactorily controlled conditions is necessary for the advancement of knowledge regarding living things and that such experimentation is continually subject to the threat of legislative interference. Chauncey D. Leake, Ph.D., Dallas, is chairman of the Southwestern Section and Dr. Donald H. Slaughter, Dallas, secretary (THE JOURNAL, Oct. 14, 1944, p. 446).

Industrial Hygiene Meeting.—The tenth annual meeting of the Industrial Hygiene Foundation will be held at the Mellon Institute, Pittsburgh, November 14-15. John F. McMahon, managing director, will open the program with a talk on "The Foundation in War and Peace." Among other speakers are:

Major Gen. Lewis B. Hershey, Washington, D. C., Industry Needs the Veteran.
Dr. Clarence O. Sappington, Chicago, A Foundation Survey of Industrial Health Departments.
Dr. Leroy U. Gardier, Saranac Lake, N. Y., Dr. Arthur G. Cranch, New York, Dr. Lloyd E. Hamlin, Chicago Heights, Ill., and Dr. Oscar A. Sander, Milwaukee, Accurate Diagnosis of Silicosis—Possible Sources of Error.
Francis R. Holden, Ph.D., Wilkingsburg, Pa., and E. C. Hyatt, Pittsburgh, Accurate Measurement of Silicosis Hazards—Newer Methods.
W. C. L. Hemeon, M.S., Pittsburgh, Findings from Foundation Plant Surveys.

Putting the Disabled Veteran Back to Work, a continuation of the panel discussions at the 1944 and 1945 meeting of the foundation, will be discussed by:

Dr. Harold A. Vonachen, Peoria, Ill., Utilizing the Physically and Mentally Handicapped Worker.
Michael Supa, Utilizing the Blind Worker.
Major Gen. Paul R. Hawley, Activities of the Veterans Administration.
Col. John N. Andrews, Washington, D. C., and I. Dent Jenkins, Lockport, N. Y., Comments on Case History Successes and Failures.

Mead Johnson and Company B Complex Award.—Nominations are solicited for the 1946 award of \$1,000 established by Mead Johnson and Company to promote researches dealing with the B complex vitamins. The recipient of this award will be chosen by a committee of judges of the American Institute of Nutrition and the formal presentation will be made at the annual meeting of the institute in the spring of 1946. The award will be given to the laboratory (nonclinical) or clinical research worker in the United States or Canada who, in the opinion of the judges, has published during the previous calendar year January 1 to December 31 the most meritorious scientific report dealing with the field of the B complex vitamins. While the award will be given primarily for publication of specific papers, the judges are given considerable latitude in the exercise of their function. If in their judgment circumstances and justice so dictate, it may be recommended that the prize be divided between two or more persons. It may also be recommended that the award be made to a worker for valuable contributions over an extended period but not necessarily representative of a given year. Membership in the American Institute of Nutrition is not a requisite of eligibility for the award. To be considered by the com-

mittee of judges, nominations for this award for work published in 1945 must be in the hands of the secretary by January 10. The nominations should be accompanied by such data relative to the nominee and his research as will facilitate the task of the committee of judges in its consideration of the nomination. Herbert E. Carter, Ph.D., Noyes Laboratory of Chemistry, University of Illinois, Urbana, Ill., is secretary of the American Institute of Nutrition.

Seminar for Study of Dental Medicine.—The second annual Seminar for the Study and Practice of Dental Medicine was held in Palm Springs, Calif., October 7-12. Participants in the seminar were members of the dental profession, medical profession and research workers in the biologic sciences. The primary aim of the meeting was to study the prevention and eradication of diseases of the mouth and related areas. Among the subjects scheduled for presentation and discussion were recent advances in nutrition, endocrinology, physiology of body fluids, psychosomatic medicine and dentistry, and pathology of teeth, osseous structures and blood. Attendance at the conference was limited in number because of the seminar character of the meeting. In accord with the need for "refresher courses" for professional men returning from service with the armed forces, special consideration was given to the applications of men reentering civilian practice after military service. The seminars were approved and sponsored by the Divisions of Educational Courses of the Southern California State Dental Association, the California State Dental Association, the Oregon State Dental Association and the British Columbia Dental Association.

Tropical Medicine Meeting.—The American Society of Tropical Medicine will hold its annual meeting in Cincinnati November 13-15 under the presidency of Dr. Rolla E. Dyer, Washington, D. C. Among the speakers will be:

Manuel Martinez Baez, Salubridad y Asistencia, Mexico, and Dr. E. Harold Hinman, Mexico, D. F., Opportunities for Training and Research in Tropical Medicine and Public Health in Mexico.
Victor P. Bond, Dr. Warren L. Bostick, San Francisco, Eder Lindsay Hansen and Dr. Hamilton H. Anderson, San Francisco, Pathologic Studies in Monkey Amebiasis.
Lieut. Col. James H. Dwinelle, M. C., Lieut. Col. Charles R. Rein, M. C., Lieut. Col. Thomas H. Sternberg, M. C., Major Albert J. Sheldon, M. C., Preliminary Report on the Evaluation of Penicillin in the Treatment of Yaws.
Major Theodore E. Woodward, M. C., Lieut. Col. Cornelius B. Philip, M. C., and Lieut. Col. Ralph R. Sullivan, M. C., Tsutsugamushi Disease (Scrub or Mite-Borne Typhus) in the Philippine Islands During American Reoccupation in 1944-1945.
Drs. George T. Harrell, John Ayera and Ellard M. Yow, Winston-Salem, N. C., An Attempt by Feeding to Induce in Animals Reactivity to Trichinella Spiralis in the Absence of Infection.

Papers to be presented will cover a wide range of subjects on tropical medicine, some discussing cutaneous diphtheria and chemotherapy of human filariasis. The tenth Charles Franklin Craig Lecture on Tropical Medicine will be delivered by Col. Paul F. Russell, M. C., Washington, D. C., on "Lessons in Malariology from World War II." A feature of the meeting will be the presentation of the Bailey K. Ashford Award.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended October 27 have been received from the division of public health methods, U. S. Public Health Service, as follows:

Foreign Letters

LONDON

(From Our Regular Correspondent)

Oct. 6, 1945.

The Threatened Decline of the Population of Britain

In March 1944 a royal commission was appointed to investigate the course, causes and consequences of British population trends and to make recommendations on population policy. During fortnightly meetings over a period of eighteen months the commission has taken practically all the general evidence needed, but some further investigation on family size remains to be done with a sample census of 10 per cent of the 14 million married women in Britain. At the outbreak of war in 1939 it appeared that the British population would soon begin to decline. The chief factor was the fall in the average size of the family, which began in the decade of 1870. Until then married women had on an average more than 5 children. By 1930 the number was down to about 2, which made no allowance for children who died young or did not marry. The full effect of the fall in average size of family on population was not manifest until the early years of the present century, when the annual number of births began to decline. In the decade 1900-1909 the annual number of births was 1,064,000; by 1930-1939 it had sunk to 701,000, producing a profound change in the age distribution of population. In 1919 there were approximately 16 million persons under the age of 20 and in 1939 only 14 million. The war introduced a complication. The number of births in 1939 was 706,000; it dropped to 693,000 in 1940 and to 669,000 in 1941. Then began a striking rise to 745,000 in 1942, 778,000 in 1943 and 841,000 in 1944. This rise can be explained by the disappearance of unemployment and the family allowances paid to men in the fighting forces. The result was more and earlier marriages. But such a rise could not continue, if only because there were not enough girls of marriageable age. By 1943 the number of marriages was below prewar level.

In investigating the causes of the decline of the birth rate the commission found no evidence that it was due to any biologic failure or to any increase of the pathologic causes of sterility. But there was ample evidence that the immediate cause was the widespread practice of birth control. What determined the size of a family was, increasingly, the ideals and sentiments of men and women, their sense of responsibility to themselves and the community and their hopes and fears for the future. For a long time the economic and social pressures favored the small family. The commission is now examining evidence on ways and means to reduce these pressures and to encourage parenthood. Its report will be the one authoritative pronouncement on the serious question of the population of Britain.

The Wellcome Historical Medical Museum's Studies in the History of Medicine: The Development of Inhalation Anesthesia

The Wellcome Historical Museum was founded and endowed by the late Sir Henry Wellcome of the firm of Burroughs Wellcome and Co., who bequeathed his fortune for advancement of medical science. The museum has arranged to publish the first of its postwar series of Research Studies in the History of Medicine. This will be a work on the development of inhalation anesthesia, by Dr. Barbara M. Duncan of the Nuffield Department of Anesthetics, University of Oxford, and formerly on the staff of the Wellcome Historical Medical Museum. The work deals exhaustively with the history of inhalation anesthesia in England, in the United States and on the European continent from the scientific and clinical points of view. It shows as well the influence of the general current of events on this branch of surgery. Important features of the work are investigation of the

various changes of opinion in regard to the physiologic action of anesthetics, the evolution and practical application of inhalers and other apparatus and the introduction of anesthetic drugs during the period under review. The work, which is illustrated by over 160 photographs and drawings, should prove of special interest to the student of medical history, since it shows how modern anesthetic methods have grown from nineteenth century beginnings. It also should be of great practical value to anesthesiologists and research workers in anesthetics. The book will make approximately 600 pages.

Demobilization of Doctors

Dissatisfaction continues to be expressed at the slowness of the demobilization of doctors. The air force has announced that it proposes to continue the same ratio as during the war, namely 2.3 medical officers per thousand other ranks. This contrasts with 0.7 civilian doctor per thousand of population, at which the *Lancet* expresses astonishment. The medical demands of the navy also are criticized. It is argued that something more could be done in calling up more civilian doctors to replace those in the fighting services. This of course would not relieve the shortage, but it might remove the bitterness growing among service doctors who feel that they are being unfairly treated. As stated in a previous letter, civilian medical appointments which become vacant are being kept open so that doctors in the services can apply for them on release. The *British Medical Journal* has decided that advertisements of permanent medical appointments which do not invite applications from service doctors and allow at least four months for the receipt of applications shall be refused publication.

Physicians and the Plan of Social Security

The plan of social security described in a preceding letter to *THE JOURNAL* has given rise to discussion among French physicians, who are dissatisfied with the present bureaucratic organization of the *Caisses d'assurances sociales* (social insurance funds). The critics of the new plan propose mutualization, the division of funds and the free choice of affiliation; this in their opinion would be a better solution than the unification of social insurance. They oppose the proposed regulation that the insured be represented by syndicates. They believe that close collaboration of the insured in the management of the funds would be more effective if the latter elected directors directly. They regret that such a small representation (two delegates) has been given to physicians. The critics deplore the fact that the medical profession has not been given a greater responsibility in the working out of the text of the law. Physicians who are in favor of this law remark not only that it offers social and medical advantages, for instance the possibility of a larger system of preventive medicine, but that it is favorable to the medical profession. The unification of the funds on the departmental basis, the amalgamation of accident insurance in the social insurance fund, is bound to facilitate the administrative work of physicians. At the present time physicians are annoyed by the tedious clerical work of signatures and accounts, from which they will be more or less freed and consequently enabled to devote themselves to treating the sick. Extension of the social insurance system to all salaried and other workers will certainly increase the frequency of consultations. They appreciate the disappearance of private funds, which are commercial concerns and whose existence is contrary to the principle of social security. The participation of doctors in the management of the Social Insurance Institution will also enable them to protect the medical point of view.

In any case, all doctors insist on the enforcement of the three principles of (1) freedom for patients to choose their own doctor, (2) freedom for doctors to adopt any therapy and (3) professional secrecy.

Treatment of Hyperthyroidism by Aminothiazole

Thiourea and its related substance thiouracil are at present considered to be the most active agents in the treatment of hyperthyroidism. Experiments have been made in France with aminothiazole, otherwise called Abadol with the chemical structure:

The efficacy of this agent was discovered by chance. On workers handling aminothiazole, a substance which was used to prepare sulfathiazole, Dr. Jeantet of Lyons noticed an abnormal development of goiters, but without ill effects and with signs of hypothyroidism and lowering of the basal metabolism. It was sufficient to transfer the worker from one department to another to verify that the thyroid body resumed its normal size. On the contrary, the condition of hyperthyroid subjects working in the same factory was improved.

Mareel Perrault, Bovet, Prognat, Coumel and others explained their experimental and clinical studies on this substance at the meeting of the Société médicale des hôpitaux de Paris. Functional and subjective signs improve rapidly. Tremor is quickly suppressed. Tachycardia disappears and the pulse becomes normal. The weight increases by several kilograms. The basal metabolism is lowered to normal. The amount of cholesterol increases by 40 per cent, but the size of the goiter and exophthalmos does not appear to be influenced by this treatment. Aminothiazole has been administered to hyperthyroid patients in tablets of 0.1 Gm. at a rate of four a day during three to four weeks. Improvement persists in some patients after suspension of the treatment: in others, relapses take place after some weeks. Aminothiazole has not to the present time produced any toxic accidents, as mentioned by various authors, in England and in the United States in the treatment of hyperthyroidism by thiourea and thiouracil.

Second Interallied Surgical Conference on the Study of War Wounds

The second Interallied Surgical Conference took place at the military hospital Val de Grace with General Inspector Dr. Rouvillois presiding, assisted by General Inspectors Jane and Maissonnet. A considerable number of American, British, French and Belgian surgeons were present. Questions pertaining to the treatment of shock and of thoracic, abdominal and thoracic abdominal wounds were discussed, as well as cranial wounds. It was stated that local and general use of sulfonamides and penicillin constituted considerable progress for thoracic war surgery, especially penicillin injected intrapleurally. The same results were obtained in the treatment of cranial wounds, above all in the prevention of infectious complications and in the treatment of existing infections.

In the treatment of abdominal wounds, sulfonamides and penicillin did not give the anticipated results.

The conference emphasized the importance of care and of the postoperative treatment of abdominal thoracic and above all of cranial wounds. The latter ought, on principle, to be treated by neurosurgeons.

Purulent chronic pleurisy with fistulas is much less frequent than after the war of 1914-1918; in the treatment of abdominal wounds the surgical results are twice as favorable as in the last war. The third conference will take place early in November.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, Sept. 26, 1945.

Work Against Leprosy

Leprosy is a health problem of prime importance in Brazil, since there are about 50,000 cases of this disease. This explains the recent creation in the Ministry of Health of the National Institute of Leprosy with a research program and coordination of all the government and private activities in this field. The experimental studies will aim at the problems of pathology, diagnosis and treatment of the disease, as well as at its epidemiology and prevention. Before the creation of this institute the Ministry of Health, through the routine activity of the Division of Leprosy of the National Department of Health, was stimulating all sorts of investigation in this field. The Division of Leprosy has awarded cash prizes for the publication of standard monographs on such subjects as the history of leprosy in Brazil, the geographic distribution of the disease and the clinical and laboratory diagnosis of leprosy, by Drs. Armando Berti, Lauro de Souza Lima and Nelson Souza Campos respectively. An important meeting of South American leprologists was held recently at Tres Corações, in the state of Minas Gerais, under the chairmanship of Dr. Christiano Machado, state health commissioner. The meeting was sponsored by the Societies of Leprosy of the states of Minas Gerais and São Paulo and by the health authorities of the two states as well as by the Brazilian federal government. The meeting was held at the Santa Fé Leprosarium in the vicinity of the city of Tres Corações, one of the largest institutions of its kind in the country. The subject for discussion was the classification of leprosy. Besides Dr. Machado, some fifty Brazilian specialists were present, among them Dr. Ernani Agricola, head of the Division of Leprosy of the National Department of Health, Dr. Nelson Souza Campos, head of the Service of Leprosy of the state of São Paulo, and Dr. Orestes Diniz, head of a similar organization of the state of Minas Gerais.

American Visceral Leishmaniasis in Vivo

A second case of autochthonous American visceral leishmaniasis in vivo has been recently reported by Dr. Armando Tavares, a pediatrician of Recife, state of Pernambuco, Brazil. The patient, a child, was treated and cured. Dr. Penna, a Brazilian physician working for the International Health Division of the Rockefeller Foundation, reported in 1934 the first instance of autochthonous kala-azar, or visceral leishmaniasis, in the Western Hemisphere in a sample of liver taken for a routine postmortem viscerotomy. Within the period of a few months 35 additional samples of liver were ascertained as positive, making up a total of 36 cases. Except for 2 cases from the Amazon Valley, all the rest were from the northeastern section of Brazil, where anti-yellow fever work is furthest developed and viscerotomy examinations are most abundant. The studies of Penna were confirmed during 1936 by Evandro Chagas and his co-workers of the Oswaldo Cruz Institute of Rio de Janeiro, who described a new species, *Leishmania chagasi*, and Dr. Alvaro Figueiredo of Recife, who reported a case diagnosed after death, the diagnosis having been based on the clinical picture and the formol-gel test. During the period 1936-1945 several instances of positive results were reported in liver samples from almost all the tropical sections of South America.

Early in 1941 Dr. Armando Tavares reported, to the Medical Society of the State of Pernambuco, the first case of American visceral leishmaniasis in vivo. The patient was a child aged 2 years from the country section of the state of Pernambuco presenting irregular fever dating from several months, diarrhea, profound anemia, a large abdomen in contrast to generalized emaciation, palpebral edema, enormous splenomegaly and slight hepatomegaly. The puncture of the spleen permitted the posi-

tive diagnosis of kala-azar. In spite of an intensive treatment with Neostibosan the child died, and the samples of liver taken from the body were considered typically positive by Dr. Lobato Paraense of the Division of Pathology of the Oswaldo Cruz Institute. The new case concerns a child aged 4 years, also from a country district of Pernambuco, who had fever and splenomegaly for two months. Treated unsuccessfully for malaria, the patient was brought to Recife. A puncture of the spleen was made which gave a typically positive result. This patient, treated specifically with injection of antimony preparations (Antimonialine and Antimonil) two months after the onset of the illness, recovered rapidly. Dr. Tavares points out that this second case presented an interesting symptom that did not occur in the first one: severe pain in both hypochondria, which progressively disappeared as the treatment advanced.

A Modification of the Ziehl-Neelsen Staining Method

Dr. J. Pitanga Santos recently published a paper in which he reports a modification of the Ziehl-Neelsen method of staining sputum smears for the search of tubercle bacilli. The new method differs from the Ziehl-Neelsen routine procedure only in the discoloration stage, which is performed by the use of a 25 per cent solution of sulfuric acid in distilled water instead of the common 2 per cent concentrated hydrochloric acid in ethyl alcohol, acting for at least ten minutes. Dr. Santos emphasizes that the tubercle bacillus stands the discoloration reaction even when this stage of the procedure is continued for about twenty minutes. This is the main point in the modification, since all other acid-alcohol fast germs are discolored when the sulfuric acid solution acts for ten minutes. In most cases the only acid-alcohol fast germ found in the human sputum is the tubercle bacillus (human and bovine types). Other acid fast bacilli may be found in sputum: *Mycobacterium leprae*, *M. lacticola* and some filaments of *Actinomyces* as well. Dr. Pitanga Santos states that, using his modification during the present year in the laboratory of a tuberculosis clinic of the Rio de Janeiro City Health Department, he has examined 1,272 samples of sputum of suspected cases, with 337 positive results, or 26.49 per cent. All these cases were considered positive for tuberculosis on the basis of the x-ray examination and the clinical findings.

Meeting of Brazilian Ophthalmologists

The twenty-third annual meeting of the Brazilian Society of Ophthalmology was held at Rio de Janeiro, September 1-6. The principal topics discussed at the meeting were the present conditions of ophthalmology in the United States (Dr. Geraldo Queiroga), the treatment of ocular syphilis (Dr. Mendonça Barros), the operation of pterygium (Dr. Laborne Tavares), ocular plastic surgery (Dr. Loch Junior), sutures in the operation of cataract (Dr. Caldas Brito), heterophoria (Dr. Nicolino Machado), binocular vision of the strabie (Drs. Paula Filho and Barbosa da Luz) and fundus oculi of the young child (Drs. L. Assumpção Osorio and Meton de Alencar). Several inspection trips were made, and a few operations were performed during the days of the meeting.

Honoring Col. Marques Porto

Several ceremonies have taken place to honor Col. Marques Porto, head of the medical service of the Brazilian expeditionary force which operated in Italy during the last eleven months of the war. In a luncheon at the Brazilian Automobile Club, after several speeches commending the work of this leading army physician, Col. Marques Porto presented a condensed report of the achievements of the medical service under his direction. During these eleven months 10,536 wounded, sick and injured officers and soldiers were admitted to the Brazilian sections annexed to American military hospitals in Italy. Of this total 9,137, or 86.7 per cent, have recovered.

Only 49 died as a result of wounds or diseases, the low fatality rate of 0.49 per cent. These good results, Colonel Porto pointed out, derived from the learning, by Brazilian physicians, of the new American war medical methods and the cordial cooperation of the U. S. Army Medical Corps. A special meeting was held by the National Academy of Medicine of Rio de Janeiro at which Drs. Leonel Gonzaga, Estelita Lins, C. Implido de Santana and Oliveira Botelho spoke in praise of the distinguished services of Col. Marques Porto.

Personal

Dr. Octavio Rodrigues, Lima, has been appointed professor of obstetrics at the University of Rio de Janeiro, succeeding Dr. Fernando Magalhães. Dr. Rodrigues, Lima, an able practitioner of the specialty at Rio de Janeiro, is son of the late Dr. A. Rodrigues Lima, who was also a leading obstetrician and for some time a member of the House of Representatives of Brazil during the twenties.

Dr. J. P. Fontenelle, professor of Public Health Administration of the Course of Public Health of the Instituto Oswaldo Cruz, has resigned the post of director of the Division of Health Information of the Rio de Janeiro City Department of Health. Dr. Paulo P. da Rocha has been appointed in his place.

Lieut. Comdr. Moacyr Itapicurú Coelho of the Brazilian Navy Medical Corps died at the age of 37 when the cruiser *Bahia* exploded in the South Atlantic last month.

Dr. Carlos V. Costa Lima of the Brazilian Navy Medical Corps has been promoted to the grade of rear admiral and appointed surgeon general of the same corps.

After the regular competitive examinations, Drs. Roberto Pimenta de Mello, Ernani Martins da Silva, Eitel Moreira Duarte, Gobart A. Costa, F. Rocha Lagoa, Haity Moussatché and Ulysses Vianna Dias have been appointed to the Instituto Oswaldo Cruz of this city. The first two of these new members of the institute will work in the division of hematology, the third in the division of pathology, the fourth and fifth in the division of bacteriology and the last two in the division of physiology.

Dr. Einor H. Christopherson, formerly head of the American Technical Mission which worked jointly with the Special Service of Public Health (the SESP), the main project of which is the sanitation of the Amazon Valley, has been awarded by the Brazilian government the medal of the *Cruzeiro do Sul* (Southern Cross) in recognition of his meritorious services to the health of Brazil. The ceremony of the bestowal of the decoration took place at the Itamaraty Palace, where the Brazilian state department is housed.

Marriages

WILLIAM HUTCHINSON SPRUNT III, Winston-Salem, N. C., to Miss Priscilla Wood Perry of Washington, D. C., September 28.

CHARLES RUPERT McADAMS JR., Belmont, N. C., to Miss Bette Jane Silcox of Philadelphia in New Orleans, September 14.

JOSEPH HARTSHORN PERRY III, Wynnewood, Pa., to Miss Marian Elizabeth Goodale of Millintown, August 4.

THOMAS LEWIS MARTIN, Greenville, S. C., to Miss Eyleen Miriam Runge at Belton, August 31.

DURWOOD J. THIBAU JR. to Miss Marie Solorge Derelle, both of New Orleans, recently.

HERMAN F. FLANIGIN JR., Oklahoma City, to Miss Thelma Thiessen of Hydro, July 29.

ABRAHAM KOSITSKY, Drake, N. D., to Miss Susan Shore in Ottawa, Ont., August 5.

ROLAND L. KLEEBERGER to Miss Lois Marie Melichar, both of Omaha, June 30.

Deaths

Fauntleroy Flinn, Decatur, Ill.; Medical College of Virginia, Richmond, 1914; specialist certified by the American Board of Radiology, Inc.; member of the American Medical Association, Radiological Society of North America, Inc., and the American College of Radiology; past president of the Decatur Medical Society; past president and secretary of the Illinois Radiological Society; at one time with the U. S. Bureau of Mines; member of the advisory board of the state division of cancer control; supervised the x-ray and radiologic departments at St. Clara's and Deaconess hospitals in Lincoln. St. Anthony's Hospital in Effingham, Shelby County Memorial Hospital in Shelbyville and the Kirby Hospital in Monticello; on the staffs of the Wabash Employees' Hospital and St. Mary's Hospital, where he died July 26, aged 55, of chronic myocarditis.

Albert Henry Andrews, Chicago; State University of Iowa College of Medicine, Iowa City, 1889; member of the American Academy of Ophthalmology and Otolaryngology and the American Broncho-Esophagological Association; specialist certified by the American Board of Otolaryngology; from 1933 to 1944 instructor in otolaryngology at Northwestern University Medical School; formerly associate professor of otology, laryngology and rhinology at the Illinois Post-Graduate Medical School; on the staff of the Wesley Memorial Hospital; oculist and aurist, Chicago, Rock Island and Pacific Railway System; died October 1, aged 83.

Adam D. Schlotthauer ☉ Newport, Wash.; College of Medical Evangelists, Loma Linda-Los Angeles, 1918; served as health officer of Pend Oreille County; at one time superintendent of the Walla Walla Sanitarium in College Place; on the staff of St. Luke's Hospital in Spokane, where he had served as vice president of the staff; on the staff of the Newport Community Hospital; past president and charter member of the Kiwanis Club; died in the Deaconess Hospital, Spokane, July 16, aged 65, of intestinal obstruction, postoperative to gastric resection for duodenal ulcer.

James Henry Keeling, Knoxville, Tenn.; New York Medical College and Flower Hospital, New York, 1914; member of the American Medical Association; president of the state board of medical examiners; awarded the Purple Heart and decorated by the British for service during World War I; served as an examiner of draftees for World War II, receiving a citation from President Roosevelt for his extraordinary work in that capacity; on the staff of Fort Sanders Hospital, where he died September 1, aged 54, of rheumatoid arthritis.

George Randolph Harris ☉ Pittsburgh; University of Pittsburgh School of Medicine, 1914; served as secretary and executive secretary of the Allegheny County Medical Society; committee member and delegate to the Medical Society of the State of Pennsylvania, in which he held the office of speaker of the House of Delegates at the time of his death; served during World War I; for many years examiner for the Civil Aeronautics Administration; formerly on the staff of the Passavant Hospital; died October 2, aged 54, of massive cerebral hemorrhage.

Enos B. Allen, Trenton, N. J.; Cleveland Homeopathic Medical College, 1899; on the staff of the William McKinley Memorial Hospital; died July 31, aged 71, of coronary occlusion.

James Ellison Anderson, Fearn Springs, Miss.; University of Louisville (Ky.) Medical Department, 1910; died July 25, aged 59, of pulmonary tuberculosis.

Elmer Eugene Babcock, Redlands, Calif.; College of Physicians and Surgeons of Chicago, 1884; died July 15, aged 86, of heart disease.

Joseph Henry Baker, Aliquippa, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1893; died July 28, aged 80, of senility.

William Franklin Baker, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1898; served on the faculty of his alma mater; past president of the Philadelphia County Homeopathic Medical Society; formerly superintendent of St. Luke's Hospital; died in the Episcopal Hospital June 27, aged 69.

Joseph DeVere Barber, Westerly, R. I.; College of Physicians and Surgeons, medical department of Columbia College, New York, 1893; member of the American Medical Association; on the staff of the Westerly Hospital; died July 27, aged 74.

Joshua R. Bechtel, Lawrence, Kan.; Kansas Medical College, Medical Department of Washburn College, Topeka, 1900; member of the American Medical Association; on the staff of the Lawrence Memorial Hospital; died July 26, aged 80, of arteriosclerosis.

James R. Bell, Fairfield, Neb.; Ensworth Central Medical College, St. Joseph, Mo., 1907; died in the Mary Lanning Memorial Hospital, Hastings, July 30, aged 72, of heart disease.

Elmer Elsworth Bowser, Tulsa, Okla.; Howard University College of Medicine, Washington, D. C., 1914; affiliated with the State Hospital for Negro Insane in Taft; died July 8, aged 58.

Howard Conley Brashear ☉ Mexico, Mo.; St. Louis University School of Medicine, 1917; fellow of the American College of Surgeons; served in the medical corps of the U. S. Army during World War I; staff surgeon at the State Hospital in Fulton; member of the consultant staff of the Ellis Fischel Hospital in Columbia and staff member of the Audrain Hospital; died July 27, aged 54, of carcinoma of the lung.

Frank Nesdill Bresnihan ☉ Cambridge, Mass.; Tufts College Medical School, Boston, 1913; died in the Somerville (Mass.) Hospital July 29, aged 59, of congestive heart disease.

Embry Allen Buckley, Little Rock, Ark.; University of Tennessee Medical Department, Nashville, 1908; for many years affiliated with the Republic Mining and Manufacturing Company Hospital in Bauxite; died in the Baptist State Hospital July 14, aged 61, of coronary thrombosis.

Peter Alfonso Callahan, Philadelphia; Jefferson Medical College of Philadelphia, 1927; served as a captain in the medical corps, Army of the United States, from July 1942 to Aug. 23, 1943, when he was released from active duty; died in the Nazareth Hospital May 22, aged 47, of bronchopneumonia.

Lowell Holbrook Chamberlain ☉ Des Moines; Jefferson Medical College of Philadelphia, 1900; also a graduate in pharmacy; member of the Society of American Bacteriologists; died July 22, aged 68, of second degree burns resulting from an accidental explosion.

Louis Warren Chilton Sr., Goliad, Texas; Louisville (Ky.) Medical College, 1890; county health officer; died in Balmorhea July 4, aged 77, of coronary thrombosis.

Fount Randall Boyd Coggin, Waverly, Ala.; University of Alabama School of Medicine, 1911; member of the American Medical Association; died in LaFayette July 9, aged 67, of pneumonia and heart disease.

Albert S. J. Collins ☉ Monticello, Ark.; Memphis (Tenn.) Hospital Medical College, 1894; honorary member of the Arkansas Medical Society; served as coroner for Monticello; died in Little Rock July 27, aged 74, of arteriosclerotic heart disease and hypertrophy of the prostate.

Arthur Rockwell Couch, Hartford, Conn.; New York Homeopathic Medical College and Hospital, 1905; member of the American Medical Association; past president of the city board of health; on the staff of the Hartford Hospital; died July 9, aged 66, of coronary thrombosis and cirrhosis of the liver.

Robert Roscoe Cutler, Washington, Mo.; St. Louis College of Physicians and Surgeons, 1915; member of the American Medical Association; president of the Franklin County Medical Society; served during World War I; on the staff of St. Francis Hospital; died July 5, aged 56, of coronary occlusion.

Ross Gilbert Downs, Newark, Ohio; Ohio Medical University, Columbus, 1897; member of the American Medical Association; died in St. Anthony's Hospital, Columbus, July 4, aged 76, of abdominal cancer.

Thomas Latane Driscoll, Columbia, Va.; University of the South Medical Department, Sewanee, Tenn., 1906; member of the American Medical Association; at one time on the faculty of the Medical College of Virginia, Richmond; served during World War I; a major in the medical corps, Army of the United States, during World War II; relieved from active duty April 17, 1943; attending physician at the Cumberland prisoner of war camp; died May 30, aged 61.

William LaFayette Freeman ☉ St. Cloud, Minn.; Rush Medical College, Chicago, 1903; on the staffs of the Veterans Administration Facility and St. Cloud Hospital; died July 18, aged 64, of coronary thrombosis.

Edgar S. B. Geesaman, Fort Calhoun, Neb.; John A. Creighton Medical College, Omaha, 1912; member of the American Medical Association; died July 16, aged 57, of coronary thrombosis.

Howard Alva Garner, Hama, Ind.; Indiana University School of Medicine, Indianapolis, 1920; member of the American Medical Association; past president of the La Porte County Medical Society; county deputy coroner; died in the Porter Memorial Hospital, Valparaiso, July 18, aged 56, of cerebral hemorrhage.

Logan Gragg, Lexington, Ky.; Medical College of Ohio, Cincinnati, 1891; member of the American Medical Association; died July 26, aged 77, of heart disease.

Robert Bragg Hagood, Lowndesboro, Ala.; Medical Department of Tulane University of Louisiana, New Orleans, 1905; member of the American Medical Association; died July 31, aged 65, of bacterial endocarditis.

John William Handy, Flint, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1884; member of the American Medical Association; emeritus member of the Michigan State Medical Society; past president of the Genesee County Medical Society, which honored him in 1934 when he completed fifty years in the practice of medicine; died July 28, aged 92, of cerebral thrombosis and arteriosclerosis.

Julian E. Hanna, Noblesville, Ind.; Medical College of Indiana, Indianapolis, 1905; died July 29, aged 74, of carcinoma of the pancreas.

Arthur Gordon Hodgins @ Honolulu, Hawaii; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1896; fellow of the American College of Surgeons; past president of the Hawaii Territorial Medical Association; served as a member of the Territory of Hawaii Board of Health; surgeon, Queen's, Kapiolani Children's and St. Francis hospitals, and Kapiolani Maternity Home; died in July, aged 69.

Howard Edward LeCates, Delmar, Del.; University of Maryland School of Medicine, Baltimore, 1913; member of the American Medical Association; physician for the Pennsylvania Railroad; member of the library commission of Delmar; on the staff of the Peninsula General Hospital, Salisbury, Md.; died July 19, aged 57.

Christopher Fahrner Mack, Richmond Hill, N. Y.; New York University Medical College, 1898; died in Forest Hills, July 23, aged 79, of intestinal carcinoma.

James Edgar Maulding, Washington, D. C.; Howard University College of Medicine, Washington, 1897; died in the Washington Sanitarium, Takoma Park, Md., August 6, aged 77, of congestive cardiac failure and coronary arteriosclerosis.

Charles Knight McCarthy, Webster City, Iowa; Tufts College Medical School, Boston, 1930; member of the Ameri-

LIEUT. JOSHUA WARFIELD BAXLEY III
(MC), U.S.N.R., 1916-1944

CAPT. JAMES CANFIELD FISHER
M. C., A. U. S., 1913-1945

MAJOR BARNEY LIHN
M. C., A. U. S., 1909-1944

Joseph Harold Henry, Detroit; Detroit College of Medicine, 1906; died in Gaylord, Mich., July 18, aged 73, of angina pectoris.

Robert Y. Henry, St. Louis; Homeopathic Medical College of Missouri, St. Louis, 1891; died July 12, aged 76, of cerebral hemorrhage.

can Medical Association and the Massachusetts Medical Society; served as director of activities for the control and prevention of tuberculosis, Iowa State Department of Health; had been affiliated with the division of tuberculosis of the Massachusetts Department of Public Health; died July 10, aged 49, of coronary heart disease.

KILLED IN ACTION

Joshua Warfield Baxley III, Ellicott City, Md.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1941; interned at the University Hospital in Baltimore; began active duty as a first lieutenant (jg) in the medical corps of the U. S. Naval Reserve on July 15, 1942; attached to the U. S. S. *Bristol*; promoted to lieutenant; awarded the European-African-Middle Eastern Area campaign medal and Purple Heart; officially reported to be missing in action as of Oct. 13, 1943, having been aboard the *Bristol* when that vessel was torpedoed and sunk in the Mediterranean off the coast of Algeria; presumptive date of death Oct. 14, 1944, according to the Navy Department, aged 28.

James Canfield Fisher, Arlington, Vt.; Harvard Medical School, Boston, 1939; interned at the Newton

Hospital in Newton, Mass., and the Boston City Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on June 20, 1942; later promoted to captain; killed in action in Luzon, P. I., January 31, aged 31.

Barney Lihn, Vineland, N. J.; Temple University School of Medicine, Philadelphia, 1934; member of the American Medical Association; interned at St. Peter's General Hospital in New Brunswick; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 16, 1941; promoted to captain and major; headquarters flight surgeon, 313th Troop Carrier Group; killed in action in the European theater of operations June 7, 1944, aged 34.

Thomas Garrett Pretlow, Chester, Va.; University College of Medicine, Richmond, 1903; member of the American Medical Association; for many years county coroner; died July 8, aged 66, of coronary occlusion.

Allen Dorsey Rebo, Scott, Ark.; American Medical University, Kansas City, Mo, 1927; died July 15, aged 40, of hemorrhage from stomach and bowels and carcinoma.

Sidney Mitchell Roberts, Chicago; Loyola University School of Medicine, Chicago, 1917; served during World War I with the Civilian Conservation Corps, the induction board of the Selective Service and as a member of the adjudication board of the Veterans Administration Facility in Hines, Ill.; died in Sparta, Wis., July 16, aged 56, of coronary occlusion and diabetes mellitus.

Lily Theresa Roche, Rochester, N. Y.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; died in the Danbury (Conn.) Hospital June 8, aged 77.

Robert Arnold Schoonover @ Greensboro, N. C.; Baltimore Medical College, 1905; past president of the Guilford County Medical Society; for twenty-one years consulting physician at the Greensboro College; died in St. Leo's Hospital July 24, aged 65, of carcinoma of the rectum.

Thomas Dow Summerford, Caraway, Ark.; University of Tennessee Medical Department, Nashville, 1916; died in the Baptist Memorial Hospital, Memphis, Tenn., June 16, aged 63.

Jay Dunham Thomas, Springfield, Ohio; Medical College of Ohio, Cincinnati, 1895; at one time Clark County coroner; formerly secretary and member of the staff of the Springfield City Hospital; served as superintendent of the Clark County Tuberculosis Sanatorium; formerly tuberculosis expert with the regional offices of the U. S. Veterans Bureau in Cincinnati; died June 23, aged 77, of primary anemia.

Ansel Lee Van Horn, Chandler, Ariz.; the Hahnemann Medical College and Hospital, Chicago, 1907; served as a member of the board of directors of the local chamber of commerce; died June 28, aged 67.

William Edward West, Garnerville, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1895; formerly on the staff of the Sydenham Hospital and with St. Bartholomews Clinic, both in New York; died June 24, aged 75.

George Louis Wurtzel, New York; College of Physicians and Surgeons, Baltimore, 1912; member of the American Medical Association; served during World War I; on the

LIEUT. (JG) KENNETH J. MURRAY
(MC), U.S.N.R., 1912-1945

LIEUT. (JG) WILLIAM E. STRUBE

CAPT. MANNING LIONEL NELSON JR.
M. C., A. U. S., 1917-1945

William W. Scott, Elk Creek, Va.; Medical College of Virginia, Richmond, 1884; died July 15, aged 89, of cerebral hemorrhage.

staffs of the New York Post-Graduate Medical School and Hospital, the Reconstruction and Park East hospitals; died June 28, aged 57.

KILLED IN ACTION

Kenneth Joseph Murray, Brookline, Mass.; Jefferson Medical College of Philadelphia, 1941; interned at the Hartford Hospital, Hartford, Conn.; began active duty as a lieutenant (jg) in the medical corps, U. S. Naval Reserve, on July 12, 1943; assigned to Naval Receiving Station in Boston, Medical Field Service School at Camp Jeune, N. C., and Camp Pendleton in San Diego, Calif.; for a year before his death was on active duty in the Pacific; in February 1944 participated in the invasion of the Marshall Islands, in June that same year in the Saipan invasion and in the following month in the Tinian invasion; in October 1944 was made battalion surgeon; for his heroism on Saipan received the Bronze Star and the Presidential citation; killed in the Pacific in February, aged 32, during the invasion of Iwo Jima.

William Ernest Strube, Fort Worth, Texas; Baylor University College of Medicine, Dallas, 1941; interned at the Naval Hospital in Great Lakes, Ill.; entered the U. S. Navy as an acting assistant surgeon, lieutenant (jg) in

June 1941; began active duty in the same grade in the medical corps of the U. S. Naval Reserve on Nov. 18, 1942; for six months on recruiting duty with the Marines in San Antonio; later ordered to Butte, Mont., where he remained until he received orders to report to San Francisco for sea duty; served aboard the *Hazelwood* 1943; held the Navy-Marine Corps Medal, Purple Heart, Asiatic Pacific Area Campaign Medal and American Defense Service Medal; participated in twelve major engagements; died in the Asiatic area April 29, aged 31, of extreme multiple injuries.

Manning Lionel Nelson Jr., North, S. C.; Medical College of the State of South Carolina, Charleston, 1942; interned at the Columbia Hospital in Columbia, S. C.; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 1, 1943; later promoted to captain; killed in action in the Pacific Ocean area March 28, aged 27.

DRUGS AND PALMAR DERMATOSES

To the Editor:—The report on Dermatoses of the Hands by Drs. C. Guy Lane et al. (*THE JOURNAL*, August 4) is of considerable interest, since a hypothesis has been proposed which may be of aid to physicians in the diagnosis of dermatoses. The authors have indicated that in at least 36 per cent of their cases the cause was not known. It would seem desirable to determine the possible influence of drugs as etiologic factors. In the abstract of discussion, Comdr. Marion B. Sulzberger (MC), U.S.N.R., spoke of other factors, including certain foods or drugs, which should be considered in the differential diagnosis of dermatoses.

May I suggest that palmar lesions may be caused by a few of the well known and commonly used drugs. The sulfonamides, especially sulfapyridine, the iodine and bromine containing compounds, antipyrine, arsenic and gold compounds and insulin have been reported responsible for palmar lesions. Since the majority of these agents are used in the therapy of chronic disease, their influence on such lesions might well be overlooked unless the history of each patient is taken carefully.

Diodoquin, a hydroxyquinoline containing 60 per cent or more of iodine, may cause extensive dermatitis covering the entire body (Norman David, personal communication). In this patient the diagnosis of fungous infection was made because of tropical residence five years previously.

The authors have stressed the importance of self medication and the mistake that patients not infrequently make in believing that their dermatitis is due to a fungous infection.

Should drugs be responsible for the dermatosis, it would seem unwise to administer sulfonamides as suggested by the authors, since patients with unusual sensitivity to one chemical type may have some sensitivity to others.

Finally, it should be emphasized that infectious agents other than those noted by the authors have been responsible for palmar lesions and should be considered in the differential diagnosis.

HAMILTON H. ANDERSON, M.D., San Francisco.

Professor of Pharmacology, University
of California Medical School.

FAVISM

To the Editor:—A boy aged 2 years of Italian parentage was admitted to the hospital because of dysphagia of about eighteen hours' duration, increasing pallor and mild jaundice of about twenty-four hours' duration, vomiting, malaise and generalized weakness. The child was well nourished. The skin and sclerae had a mild icterus. There was a distinct pallor to the skin. The spleen was not palpable. The temperature was 99.8 F. Otherwise the physical examination was negative. Laboratory studies revealed 25 per cent hemoglobin, 1,390,000 red blood cells and 45,650 white blood cells with 70 per cent polymorphonuclear leukocytes and 30 per cent lymphocytes. The urine showed 10 mg. of albumin. A tentative diagnosis of acute hemolytic anemia was made, the etiology to be determined. Erythrocyte fragility tests were normal. X-ray studies of the skull revealed no changes to be compatible with Cooley's anemia. Transfusions were given and the blood picture was restored to about normal. Improvement was gratifying on the second day of admission, and for the remaining three days of hospitalization he was symptom free.

The child had eaten several fava beans just prior to the onset of his attack. Favism is an acute hemolytic anemia caused by contact with the fava bean or the plant from which it comes. This condition is relatively common in the Mediterranean

countries. To the best of our knowledge it has been reported on only three occasions in this country. The fava bean, although not common in this country, is grown and eaten by persons of Mediterranean origin in many sectors of the United States. Favism should therefore be considered when acute hemolytic anemia occurs in persons of Mediterranean origin.

It appears likely that many more cases of favism would be discovered if this condition should be kept in mind.

HERBERT E. SPAULDING, M.D.

WALTER J. LEVINSKY, M.D.

Eric, Pa.

intern, respectively, Hamot Hospital.

HEAT FOR RELIEF OF ITCHING DUE TO SENSITIVITY

To the Editor:—I was much interested in the communication of Dr. Francis E. Park in the August 15th issue of *THE JOURNAL*.

Some years ago I developed an itching of the dorsum of both feet, which was intense and kept me awake nights. After unsuccessful treatment by two dermatologists, I consulted Dr. Marion Sulzberger, who immediately recognized that I was allergic to the leather in my shoes. He advised my changing to white shoes and this effected a cure. Since then I have found that it was only tan leather or tan leather lining of black shoes which caused itching. Black shoes with black, gray or white lining caused no trouble.

Before my cure I tried many antipruritic ointments, powders and liniments with little or no relief. But I learned that immersing my feet for ten to fifteen minutes in very hot water caused at first such an intensification of the itch that, in the words of Dr. Park, "it was almost a pleasure." After that the itching was relieved for the whole night and I was able to sleep.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Massive Infection with *Trichuris Trichiura* in Children: Report of 4 Cases, with Autopsy. L. Getz.—p. 19.
*Immunity Response of Mothers and Babies to Injections of Pertussis Vaccine During Pregnancy. Pearl Kendrick, Mary Thompson and Grace Eldering.—p. 25.
Preventive Care of Infants and Children: I. First Postnatal Family Interview. C. A. Tompkins.—p. 32.

Response to Pertussis Vaccine During Pregnancy.—Kendrick and her associates report opsonocytaphagic reactions to *Hemophilus pertussis* in 99 pregnant women, of whom 57 were immunized with pertussis vaccine and 42 were nonimmunized. A pronounced rise in opsonins was observed after injections of vaccine. The ratio of the average opsonic reaction of nonimmunized to that of immunized women was 1:2. The opsonins of the babies were of a lower titer than those of their mothers; the ratio of the titers of the babies to those of their nonimmunized mothers was 1:2.2, and the corresponding ratio for the immunized group was 1:15. With respect to the babies, the ratio for the nonimmunized to the immunized group was 1:29. These results indicate that placental transfer of pertussis circulating antibodies does occur and that the higher the level in the mother, the more nearly does the titer of her baby approach her own.

Observations on Private Practice of Psychiatry. W. Muncie.—p. 111.

Psychologic Deprivation in Infancy.—A group of 15 children admitted to an institution in early infancy and remaining under institutional care for an average of thirty-two months was later transferred to foster homes. These children were paired with children who had been in foster homes and had not had other than family rearing. All the children were given

tests of intellect, language, motor coordination, social maturity and personality. Data were first gathered when the institution children were still in the institution and again after they had been in foster homes for seven months. In the first series of tests the institution children were inferior to the foster home children in intellectual performance in activities with requirements for both verbal and nonverbal reaction, in vocabulary and in language. The mean intelligence of the institution children was inferior in terms of a normal group, while the mean intelligence of the foster home group was within the average ranges. The institution children tended to be more removed in their reaction to the examiner and to the test material. The Rorschach test results tended to confirm their general immaturity in comparison to the foster home children. There were no differences in social maturity or in motor coordination. In no area were the institution children superior to the foster home children. After the institution children had had seven months of placement experience the foster home children were still superior in intellectual performance and in language performance. The institution children were no longer differentiated from the foster home children in such qualities as friendliness to strange adults and curiosity and interest in material objects. Relative to their age group, the institution children dropped in social maturity following the foster home experience. This may be due to the trauma of separation from the familiar environment. That the institution child's initial experience in placement did not diminish the gap in mental performance between institution child and foster home child seems to strengthen the hypothesis that psychologic deprivation in infancy produces a lag in mental growth which is maintained even under new conditions of enriched stimulation. The language deficiency of the institution children is a factor retarding them. An extensive period of deprivation of babies in an infant institution is profoundly detrimental to their psychologic growth.

Malaria in the United States.—During the recent war the malaria case rate in soldiers who had not been outside the continental United States has constituted a small fraction of that in the first world war. This has been due to efforts within the posts and those of public health agencies immediately around the camps. This joint control has also had its favorable effects on the nearby civilian communities. Because of suppressive chemotherapy in hyperendemic malarious areas of military operations outside the continental United States, materially aided by malaria surveys and control operations, malaria is no longer a serious clinical problem within controlled military zones. Moreover, falciparum malaria is usually liquidated by adequate

suppressive treatment, but vivax malaria is subject to repeated relapses up to two years. Thus, vivax cases among military personnel returning to the United States constitute a potential hazard. In addition, civilians and merchant seamen who have not been under strict military discipline and have been exposed to malaria overseas constitute a grave potential risk. Faust stresses the need for (1) more extensive consciousness of malaria in patients appearing for consultation and treatment, not only in highly endemic territory but in areas of milder endemicity and in nonmalarious regions; (2) increased accurate blood-film diagnosis; (3) treatment of all malaria patients with adequate amounts of antimalarial drugs until cure is effected; (4) inquiry by all physicians consulted by veterans, merchant seamen or civilians who have been overseas, regarding a history of malaria or exposure to malaria, and notification to local health authorities of potential malaria carriers; (5) a minimum food ration for the poorer elements of our population which is quantitatively and qualitatively adequate to produce resistance to disease, and (6) serious consideration of the advisability of instituting suppressive antimalarial therapy to populations in hyperendemic foci.

Immunization Against Yellow Fever.—Smithburn and Mahaffy found that protective antibody against yellow fever virus is demonstrable in the serum of rhesus monkeys within six or seven days after inoculation with standard 17D yellow fever vaccine virus. Rhesus monkeys are completely resistant to the inoculation of highly virulent pantropic yellow fever virus within five or six days after injection of 17D vaccine. This resistance is present prior to the appearance in the serum of demonstrable protective antibody. Protective antibody is demonstrable in man in a high percentage of cases by the tenth day after injection of 17D vaccine and may be present as early as the seventh day. Postvaccination surveys of immunity were made in persons inoculated in Africa with 17D vaccine and revealed the following: 1. Of the military personnel sampled one to twenty-two months after vaccination, 92.2 per cent exhibited protective antibody. 2. Ninety per cent of civilians inoculated in Kenya exhibited protective antibody in their serums twenty-three to thirty-six months after receiving the vaccine. 3. More than 90 per cent of persons vaccinated in Uganda had protective serums after three years, and there was no decline in the incidence of immunity during the third year. 4. The percentage of children who became immune as the result of inoculation was as great as that in adults, and the antibody response was equally well maintained.

Chemotherapy of Human Filariasis.—Thirty patients with filariasis (*Wuchereria bancrofti*) were treated with neostibosan for intervals ranging from thirty-three to forty-eight days. By the sixth month after treatment had ended, microfilariae had disappeared from 7 of the patients and had declined in all but 1 patient. In 15 of the 30 treated patients, over 80 per cent of the microfilariae were lost during the six months of observation. Among 15 control untreated patients with filariasis, followed for the same period as those under treatment, 13 showed an increase in microfilarias, 1 showed a small decline and 1 presented no change in the number of circulating parasites.

- *Evaluation of Toxoplasma Neutralization Tests in Cases of Chorioretinitis. J. M. Heidelberg.—p. 28.
- Herpes Zoster Ophthalmicus: Report of Cases and Review of Literature. A. E. Edgerton.—p. 40.

Cataract and Other Congenital Defects Following Rubella in Mother.—Long and Danielson report 6 cases in which mothers had contracted rubella when from two to six weeks pregnant. Three of the babies born to them presented bilateral cataracts which were associated with bilateral microphthalmos. Three babies had unilateral microphthalmos with a distinctive type of cataract in the smaller eye. Lesions were

observed in the fundi in the three eyes of this series in which the fundus could be seen. All 6 children had cardiac defects. There was 1 case each of talipes valgus, cryptorchidism, hypospadias and dacryostenosis. The authors believe that the cataracts, the microphthalmos, the lesions of the fundus and the cardiac defects are the result of intrauterine damage by rubella.

Toxoplasma Neutralization Tests in Chorioretinitis.—Heidelberg performed 269 neutralization tests in serums from 211 persons. These serums were obtained from patients with various forms of uveitis or other types of congenital or acquired ocular disease and from normal persons, including parents of patients with congenital chorioretinitis. Strong to moderate neutralization of Toxoplasma was obtained with the serum of 63 per cent of 27 patients with congenital chorioretinitis, 14 per cent of 97 patients with anterior or posterior uveitis and 10 per cent of 58 normal persons other than the parents of infants or children with congenital chorioretinitis. Of 9 patients with congenital chorioretinitis and other evidence of toxoplasmosis, only 5 had antibodies. Antibodies were present in 6 of 7 mothers of patients with congenital chorioretinitis. It would appear that the demonstration of the neutralizing antibody should be considered a factor of moderate diagnostic value only in patients with congenital chorioretinitis. Its absence from serum does not rule out the possibility of toxoplasmic infection. The neutralizing antibody is of low titer, is thermolabile and shows a tendency to disappear from the blood serum in a few weeks, although it may persist for fifteen months or longer, possibly even indefinitely in some cases. Aside from possible instances of familial infection, Toxoplasma neutralizing antibodies may be demonstrated in 10 to 14 per cent of persons without clinical manifestations of toxoplasmosis as the disease is at present understood. It is probable that in some of these persons the antibodies are nonspecific.

Precipitation Test in Infective Hepatitis.—Olitzki and Bernkopf found that 94 of 102 serums from patients with infective hepatitis gave a positive precipitin reaction with cholesterolized alcoholic extracts of liver or spleen tissue treated with ether. Antigens from normal subjects as well as from infective hepatitis cases elicited a positive reaction. Sixty-four of 330 serums from subjects with diseases other than infective hepatitis gave positive reactions. Nearly all the nonspecific positive reactions could be eliminated by prior heating of the serum (fifteen minutes at 60 C.). There is a considerable difference in antibody content between hepatitis serum and positive serums from other sources. Eighty-six per cent of the hepatitis serums gave a positive reaction even when 0.02 cc. or less of serum was employed in the test, whereas serums from other origins failed in most cases to elicit a precipitation reaction when less than 0.1 to 0.05 cc. of serum was employed. Although the test does not conform with the strict requirements of serologic diagnosis, it nevertheless demonstrates a considerable serum difference between serums of persons with infective hepatitis and those with other conditions.

Histopathology of Muscles in Progressive Muscular Atrophy.—Hassin and Dublin obtained material from a typical case of Aran-Duchenne's type of progressive muscular atrophy. They stress that progressive muscular atrophy, type Aran-

Duchenne, and progressive muscular dystrophy are the most common forms of muscular wasting. Both types possess some features that are alike but differ in their intensity and extensivity. In progressive muscular atrophy the spinal cord is severely involved, which is not the case in progressive muscular dystrophy. In both the changes are degenerative, analogous to those obtaining in muscle fibers divided by a sharp instrument. The degenerative changes in the muscles are accompanied by phenomena of myophagia, in analogy to those of neuronophagia observed in damaged central nerve fibers. The function of the myophages is like that of neuronophages, to remove the damaged tissue and render it harmless. Signs of mesodermal reaction—multiple scar formation—are absent in progressive muscular atrophy, and signs of fatty transformation (lipomatosis) are more manifest in cases of progressive muscular dystrophy. Pathologic changes justify the opinion that, in spite of the presence of Heubner's endarteritis, syphilis is not the cause of progressive muscular atrophy.

Pathologic Lesions in Western Equine Encephalitis.

According to Noran and Baker the western variety of equine encephalitis has been recognized as one of the most prevalent forms of encephalitis. In the summer of 1941 alone 1,700 cases were recorded in Minnesota and North Dakota. The lesions may be progressive, resulting in a chronic form of this illness, especially in infants and children. The authors describe the pathologic picture of a case of chronic encephalitis in which cysts had replaced both frontal lobes and were separated from one another by glial tissue. The rest of the brain presented widespread parenchymal changes consisting of diffuse and focal areas of demyelination. The vascular involvement varied from collars of perivascular infiltrates to the narrowing and occlusion of the vessels by an endothelial proliferation. Vascular calcification was prominent. In another case a progressive encephalitis had been present since infancy and had shown intermittent activity over a period of many years. At necropsy the lesions were identical to those observed in their first case. Since the Midwest epidemic of equine encephalitis of 1941 the authors have obtained brain tissue from 10 cases; 6 were obtained during the acute phase, 1 during the subacute phase and 3 during the chronic stage of the illness. The development of the main lesions could be traced through the acute, subacute and chronic stages of the disease with fair accuracy. The results suggested that the vascular alterations were primary and indicated that the parenchymatous lesions were principally secondary to the resultant cerebral ischemia. The extreme prominence of pathologic changes in the blood vessels points to a vascular spread of the equine virus.

Riboflavin, Niacin and Thiamine Content of Leguminous Seeds.—Daniel and Norris investigated the riboflavin, niacin and thiamine content of dried leguminous seeds. Seventeen varieties of legumes were analyzed. Two different methods were used for determining each vitamin in one sample of every variety of legume. Agreement was found in all cases. The methods used were the fluorometric method for riboflavin, the microbiologic method for niacin and the thiochrome method for thiamine. The results indicate that legumes are an excellent source of thiamine and a good source of niacin and riboflavin. With a few exceptions the greatest amount of all three vitamins is found in the soybean, thus substantiating its high status in the list of foods.

Kidney Function in Hypertension.—At the University Hospital of Ann Arbor, Mich., clinical estimates of kidney function are based on the composite of three tests: (1) examination of the urine for protein, casts and cells, (2) the urea clearance test and (3) the maximal concentration test. In studies on the renal function of 200 patients with essential hypertension it was found that repeated negative urinalyses are not sufficient evidence to assume that kidney function is normal. In 28 per cent of the patients included in this study renal function was impaired even though the urine showed no abnormalities on routine examination. The combination of normal maximum concentrating ability and normal urinalysis is a sufficient clinical indication of unimpaired renal function. The concentration test is more sensitive than the urea clearance test in detecting early kidney damage in essential hypertension. Thirty-three per cent of the series showed impaired concentrating ability in the presence of normal urea clearance values, while in only 3 per cent was the concentrating ability adequate in the presence of subnormal urea clearance.

Gold Compounds in Treatment of Rheumatoid Arthritis.—Cohen and his collaborators administered from 1 to 5 courses of gold compounds in the treatment of 259 patients with rheumatoid arthritis for a total of 417 courses. They found that the administration of 300 mg. of ascorbic acid daily did not reduce untoward reactions in 65 patients receiving 118 courses of gold compounds. Vitamin B complex was not a factor in reducing untoward reactions in 29 patients receiving 66 courses. The improvement was no greater in the groups receiving vitamins as an adjunct than it was in the group of 43 patients receiving 57 courses of gold compounds alone. There was one fatality due to thrombocytopenic purpura. Because of objective improvement in 88 per cent of the various courses of treatment, gold preparations are recommended for the treatment of rheumatoid arthritis, but extreme caution must be exercised. A normal sedimentation rate is not necessarily a contraindication to gold therapy. An increasing sedimentation rate during treatment is not always an indication that clinical improvement is not to be expected. There were untoward reactions in 10.3 per cent of 417 courses of treatment. There were untoward reactions in only 8.9 per cent of 259 patients receiving a single course of gold treatment. In the 96 patients receiving 2 courses the incidence of untoward reactions rose to 15.6 per cent.

Active Immunization Against Scarlet Fever.—Glazier describes a modification of Dick's method which results in fewer general reactions and a higher degree of immunity. He divided 28 patients into three groups during 1933 and 1934 and immunized by means of six, seven and eight injections respectively given at intervals of one, two and three weeks. The most effective method with the lowest incidence of general reactions was that of seven consecutive weekly injections. This method was employed in immunizing 340 children in subsequent years. The injections were given subcutaneously in doses of 650, 2,500, 5,000, 10,000, 25,000, 55,000 and 110,000 units, a total of 208,150 units. If a moderate or severe general reaction occurred, the same dose was repeated the following week. The injections were stopped if an allergic reaction occurred. Immunization was conducted during the spring or fall, preference being given to the late spring. Of 2,357 injections given, only 166 (7 per cent) produced general reactions. The most frequent of these was nausea and vomiting. Immunity, as evidenced by a negative Dick test, was complete in 98.9 per cent of the children, a repeat injection being given to the others. With such a high percentage of immunity, a follow-up Dick test is probably unnecessary. None of the 340 patients developed scarlet fever. The best age to immunize actively for scarlet fever is between 1 and 2 years. The incidence of general reactions was lowest in this group. Since there is a scarlet fever susceptibility of over 90 per cent at this age, an initial Dick test is not necessary. A history of allergic sensitivity is not a contraindication to immunization.

Effectiveness of DDT in Anopheline Control.—An average tenant house can be treated with a DDT residual spray at a cost of from \$1.50 to \$1.75, including labor, materials and overhead but exclusive of the initial outlay for heavy equipment. One treatment a year might be sufficient in the more northern malaria zones of this country, but two treatments will probably be required in the southern zones. Residual sprays do not give as effective a kill in occupied houses, not because of lack of toxicity but because of the large proportion of untreated resting places such as furniture, bedding and exposed wearing apparel. Treatment of household effects is advised where practical. Treated wood surfaces exposed to 14 inches of rainfall over a period of four weeks effected a 25 per cent kill compared with a 75 per cent kill obtained from control panels. Sunlight alone caused a reduction in toxicity of 10 per cent over the same period. When applied as a spray at the rate of $\frac{3}{4}$ pound of DDT per acre, essentially 100 per cent larva kills were obtained. Materials for effective larviciding with DDT cost less than one fifth as much as a comparable effective application of fuel oil.

Pathology of Bronchial Asthma.—Unger reports post-mortem observations on 5 cases in which death occurred in uncomplicated asthma. Emphysema was present in all 5, being present even in the 1 year old child who had asthma for only nine months. Plugging of the bronchi was present in the first 4 cases (the lungs in case 5 were not sectioned), and undoubtedly this obstruction is a very important cause of asthma. Morphine was used in cases 3 and 4, and death followed promptly. Morphine is too dangerous a drug to use in bronchial asthma because it prevents expectoration of mucous plugs. It also harms by depressing the cerebral respiratory center, with result-

tant slowing of respiration in a patient already short of oxygen. Microscopically the usual findings at death during a paroxysm are thickening and hyalinization of the basement membrane of the bronchi, eosinophilic infiltration of the bronchial and peribronchial tissues (the mucous plugs may also contain eosinophils) and excessive mucus in the lumens, varying from thin serous material to thick black obstructing plugs. In the lumens there may also be Charcot-Leyden crystals, Curschmann spirals, fibrin, erythrocytes and desquamated epithelial, round and polymorphonuclear cells. The epithelial lining may be normal or may be partially stripped off. The goblet and mucous cells are either increased or degenerated. The muscular layer is often thickened in chronic cases. The smaller bronchi and the alveoli may be more or less enlarged, depending on the degree of emphysema. As they enlarge, their lining usually thins. The submucosal layer is often widened, and there may be thickening of vessel walls.

Succinylsulfathiazole and Intestinal Suction in Surgery of Large Bowel.—Newton and Blodgett observed the use of the Miller-Abbott tube and of succinylsulfathiazole in 114 cases of large bowel resection. The general preoperative and postoperative care was the same in all except that in the test group (36 cases) preoperative succinylsulfathiazole and preoperative and postoperative intestinal suction were used. In the control group (78 cases) primary colostomy without chemotherapy was the routine in resections with restoration of continuity. The Mikulicz type of resection was not required in any cases of the test group. The following data are of statistical significance in the comparison of the two groups: 1. The gross incidence of complications was reduced from 58 to 25 per cent. 2. The gross mortality was reduced from 19 to 3 per cent. 3. When similar operative procedures (resections and anastomoses) are compared, it is found that the incidence of postoperative infection is reduced from 43 to 6 per cent and the mortality is reduced from 22 to 3 per cent.

Short Esophagus, Peptic Ulceration and Cancer.—Smithers advances a theory suggesting that both congenital shortening of the esophagus and acquired shortening due to cicatrization following ulceration are comparatively rare, and that the majority of the cases diagnosed as short esophagus radiologically are primarily cases of hiatus insufficiency associated with spasm of the longitudinal muscle fibers resulting from irritation due to flow of gastric juice into the esophagus. A lax hiatus may result either from a developmental deficiency due to delayed descent of the stomach or to a loss of elasticity of the tissues in later life. In most cases of "congenital short esophagus" the condition is not congenital and the esophagus is only shortened by spasmodic contraction. Two cases of short esophagus and cancer are added to those previously reported.

Sulfonamide Rashes in North Africa and Italy.—Peterkin examined 650 cases of sulfonamide sensitization while in service in North Africa and Italy. Of the various drugs employed, sulfonamide seemed the most apt to cause reactions, especially if used in the form of powder. The whole group of sulfonamides seemed less likely to cause reactions if applied in the form of a thick paste or a water miscible cream. The reactions were due to the treatment of many different conditions from major wounds and burns to slight grazes, impetigo and chancreoid. Only three of the sixteen types described by the author are liable to cause a grave or prolonged illness, i. e. the pemphigoid, the sulfonamide light eruption and the sulfonamide contact dermatitis. Sulfonamide light dermatitis accounted for 72.2 per cent and contact dermatitis and its complications for 17.2 per cent, i. e. 90 per cent of the total. Most cases of reaction were due to the use of sulfanilamide in powder form; the safest drugs appeared to be sulfadiazine and sulfa-

guanidine. Acriflavine can reactivate a sulfonamide light or contact dermatitis just as may cocaine. No race is exempt from this sensitization, skin color and texture making little or no difference. Sulfonamide reactions are uncommon in United States troops compared with British. This is due to the fact that the U. S. Medical Corps uses sulfonamides chiefly in the form of a 5 per cent sulfadiazine in a water miscible cream. The local application of sulfonamides is contraindicated in skin diseases, though there is little risk if the drugs are used with certain precautions. Intramuscular penicillin appears to be the treatment of choice in two types, the pemphigoid and the severe light dermatitis.

Cerebral Fat Embolism After Convulsion Therapy.—Meyer and Teare's patient, a man aged 53, had sustained gunshot wounds at the back of the right knee during the war of 1914-1918 and now complained of severe pain in this knee, with inability to straighten the leg. Under sodium amylal and suggestion therapy the patient was able to walk about freely without pain. Prolonged narcosis was given from April 30 to May 15, but no lasting improvement resulted. Psychotherapy and occupational therapy were continued until December. An electrical convulsion was given, from which the patient made a fair recovery. He died twelve hours later. The diagnosis of cerebral fat embolism was established by the microscopic evidence and was clinically suggested by the so-called free interval, although it was not entirely free of symptoms and there is some doubt whether it ended with the first collapse about twenty minutes after the convulsion or with the second final collapse about two hours later. The characteristic petechial hemorrhages of the skin were absent; in the brain only a few were encountered. Cerebral fat embolism has not been described after electrical convulsion treatment. Neither a fracture nor any of the other recognized causes of fat embolism were found post mortem.

Peripheral Arterial Embolectomy.—The leading symptom in the diagnosis of peripheral embolism is that something sudden happens in a limb. It may feel "cold and numb," "as heavy as lead," "as though it was gripped in a vice." Together with any of these there is often loss of voluntary movement. The limb is cold from 1 to 2 inches below the site of lodgment of the embolus. Pallor or cyanosis may be evident, and there may be mottling or lividity below a line of demarcation. Arterial pulsation is absent distally, while pressure over the site of the embolus causes pain. As soon as peripheral embolism is diagnosed the limb should be lowered not raised and surrounded by ice bags, not hot water bottles, as the metabolism of the anoxic tissues must be reduced. Ideally, operative removal of the embolus should be carried out within four to six hours, but delay over this time need not preclude the possibility of recovery after embolectomy. Hopkins performed successful popliteal and femoral embolectomies on a woman aged 43 thirty-nine hours after lodgment of the emboli. The convalescence was uneventful.

Chronic Amebic Dysentery.—A man who had been invalided from India, where he had been in the hospital almost continuously for a year because of chronic amebic dysentery and whose condition deteriorated in spite of two courses of standard treatment in another hospital at home, was cachectic and pyrexial, with persistent abdominal pain and some twenty foul stools daily containing blood and many amebas. In spite of six daily injections of 1 grain (0.06 Gm.) of emetine followed by a twenty-one day blunderbuss course, his condition became worse and he appeared moribund. At this state Hargreaves administered an initial dose of 100,000 units of penicillin intramuscularly followed by 33,000 units every three hours up to a total of just over 1 million units. The result was dramatic. Twenty-four hours after the treatment was begun he was free from pain and was afebrile. After two days he passed a formed stool for the first time in two years. He rapidly put on weight, but amebas were still present in the stools and after two weeks there was a recurrence of diarrhea with blood. He was given a second course of penicillin, this time $2\frac{1}{4}$ million units. Again his stools became normally formed and sigmoidoscopy revealed that the bowel was healthy. After a month's convalescence he was given another twenty-one day course of blunderbuss antiamebic treatment, as amebas were still present in the stools. Four months later six daily examinations of the stools were negative. To combat some of the organisms which are not sensitive to penicillin, the author also gives a course of succinylsulfathiazole concurrently by mouth—total 80 Gm. The author has treated 47 cases of severe refractory amebic dysentery on these lines and has rarely found more than one course of emetine bismuth iodide to be necessary afterward to cure the amebic infection. Success with penicillin and succinylsulfathiazole in chronic amebiasis led to the application of this treatment in chronic ulcerative colitis. It has been successful in several such cases.

Curare as Aid to Anesthetist.—Griffith's practice has been to administer curare only when there is need to obtain increased muscular relaxation. This may be done at any time during the operation and should be in adequate dosage (60 to 100 mg. for an adult under cyclopropane), which may be repeated but is by no means necessary in every abdominal case. A recent survey at the author's hospital in Montreal shows that, although curare is used on the slightest provocation and has been used more than five hundred times, it is still administered in only 38 per cent of abdominal operations. Curare should not be the excuse for a poor anesthetic sloppily administered. He has used cyclopropane for many years to the almost complete exclusion of ether. For this reason most of his work with curare has been on patients under cyclopropane anesthesia. The two drugs seem to make an ideal combination. Curare may also be used in ether anesthesia or when ether is combined with cyclo-

propane, ethylene or nitrous oxide; but under these circumstances the dose of curare should be greatly reduced—to an average of 20 to 40 mg. for an adult. Perhaps the most surprising outcome of the investigation on curare is the absence of evidence of toxicity in a drug with such a fabulous reputation as a poison. However, earlier physiologists worked with a comparatively crude curare which probably contained variable quantities of other adulterating substances. The new purified and pharmacologically standardized product is rapidly broken down in the human body and is completely eliminated. When improperly used, curare is still a poison capable of producing death by respiratory paralysis. Griffith feels that curare will make it possible to use the nontoxic and controllable gas anesthetic agents, particularly cyclopropane and ethylene, in a wider variety of major operations, that it will reduce the use of spinal anesthesia for upper abdominal surgery with its attendant hazards and that it will afford more efficient anesthesia with low concentrations of ether when that agent is chosen.

*Rh Factor and Blood Group Frequencies in Japanese. J. J. Graydon and R. T. Simmons in collaboration with G. A. M. Heydon and A. J. Bearup.—p. 601.
Adelaide Local Board of Health Survey of School Children by Mantoux and Patch Test. H. K. Fry.—p. 604.
Gestation Period. D. H. Sutton.—p. 611.

Rh Factor and Blood Group Frequencies in Japanese.—Graydon and his collaborators collected blood group data in relation to anthropology for different races in the Pacific. They report observations on blood samples obtained from 400 adult male Japanese. The samples were tested for blood groups and subgroups, M, N types and the Rh factor. It was found that 123 (30.75 per cent) belonged to group O, 149 (37.25 per cent) to group A, 88 (22 per cent) to group B and 40 (10 per cent) to group AB. Only 2 (1.1 per cent) of 189 samples of blood of groups A and AB were of subgroup A₂. The Japanese in this respect are similar to the Australian aborigines, Hawaiians, American Indians, Eskimos, Chinese and Indonesians in that the factor A₂ is absent or extremely rare. One hundred and fourteen (28.5 per cent) of the samples were of type M, 204 (51 per cent) were of type MN and 82 (20.5 per cent) were of type N. Three hundred and ninety-nine (99.75 per cent) of the samples were Rh positive; only 1 sample was found to be Rh negative. In respect to the Rh factor the Japanese again give a result similar to the Australian aborigines, American Indians, Chinese and Indonesians, the blood of all of which races is approximately 100 per cent Rh positive. In the white races tested only 85 per cent approximately have Rh positive blood.

Injuries Produced by Plants in Tropical Queensland. H. Flecker.—p. 636.

Prophylactic Use of Sulfanilamide in Rheumatic Fever.—Anderson reports that in August 1944 he established at the Children's Hospital in Melbourne, as a branch of the rheumatic heart clinic, a section which has been concerned with the distribution of sulfanilamide and the supervision of patients suffering from rheumatic fever who were taking the drug. The patients who were selected for prophylactic treatment with sulfanilamide had all suffered an attack of rheumatic fever one or more times during the preceding five years, usually during the previous two years. Such patients varied in age from 3 to 14 years. Of 104 children who received sulfanilamide prophylactically and who were observed for six months, 1 child had a doubtful recurrence of the disease. An average of 470 children not taking the drug formed a control series during the same

time, of whom 30 definitely suffered from recurrent rheumatic fever, and 3 possibly so; this is equivalent to a recurrence rate of 13.5 to 15 per cent per year. The toxic effects of the drug were minimal.

Metrazol Epilepsy.—Chaubard and his associates found, in experiments on rabbits, guinea pigs and rats, that metrazol injections result in an inverse modification of the excitation time on the cerebral cortex (prolongation) and the peripheral nerves (shortening). The effects of metrazol on the nervous centers are complex. The investigations conducted by the authors confirm earlier observations which attribute to the base of the brain an important part of the metrazol attack, but they go further and bring proof that the cerebral cortex, far from being stimulated by metrazol, is depressed by it. This is in accord with the fact that in man the attack is accompanied by loss of consciousness, that is, by suppression of the cortical function. In the encephalogram, under the effect of metrazol, the augmentation of voltage is on a par with a retardation of the waves which speak in favor of a depression. The authors show that the complex action of metrazol, depressing the superior centers and stimulating the inferior ones, must not be confounded with that of ordinary stimulants such as strychnine, which excites the brain and the lower centers simultaneously. Great similarity exists between metrazol epilepsy, insulin coma and electric shock, which are used in psychiatry.

- *Perforating Endometriosis of Posterior Fornix. N. Arenas and O. Blanchard.—p. 129.
Testosterone Propionate in Pain from Cancer of Uterus. J. Nemirovsky.—p. 136.

Perforating Endometriosis of Posterior Fornix.—According to Arenas and Blanchard, endometriosis of the posterior fornix may be caused by any of the following conditions: (1) endocervicitis, (2) reflux of menstrual blood, (3) rupture of an ovarian cyst, (4) implantation of decidual cells after obstetric trauma and (5) proliferation of aberrant endometrial tissue. The condition is observed, as a rule, in women between 30 and 40 years of age. The symptoms are more or less acute. There is a hypermenorrhea, intermenstrual or premenstrual bleeding, rectal pain and small rectal hemorrhages. Small, dark blue cysts and bleeding granulations partially covered by the vaginal folds are seen during the gynecologic examination. The appearance of the vaginal lesion is that of a scar. There is an early infiltration of the rectovaginal septum and later stricture of the rectum. The diagnosis is arrived at by a biopsy. The therapy consists in irradiation of the ovaries or a panhysterectomy. In the case reported by the authors, endometriosis of the posterior fornix perforated the cul-de-sac of Douglas and infiltrated the rectovaginal septum. Treatment consisted in a bilateral adnexectomy.

- *Penicillin in Tertiary Yaws. F. Nery Guimarães.—p. 89.
Cancer in Children. B. Ruy Prates.—p. 98.

Penicillin in Yaws.—Nery Guimarães reports good results with penicillin treatment of 6 patients with tertiary yaws (ulcerated gumma, periostitis, osteitis, osteoporosis and rhinopharyngitis mutilans). The Wassermann reaction was strongly positive in all. The drug was administered intramuscularly in doses of 400 Oxford units each, which was given every six hours three times a day up to a total dose which varied between 50,000 and 600,000 Oxford units during a period which varied between three weeks and seven months. Clinical recovery was

obtained in all cases. The Wassermann test repeatedly performed became negative and remained so. In cases of bone lesions, pain on pressure of the involved bone area disappeared, but the structure of the bone, as seen under the x-rays, was not entirely reconstituted. The results of penicillin in cases of bone lesions were as good as those in which arsphenamine therapy was employed. The patients are still under observation. This is a preliminary report.

- *Bronchial Carcinoma with Early Multiple Cutaneous Metastasis. F. Morán Miranda and C. G. Gonnella.—p. 1099.

Bronchial Carcinoma.—According to Morán Miranda and Gonnella, early cutaneous metastasis of primary bronchial carcinoma is rare. The metastatic nodules are multiple. They appear simultaneously with the respiratory symptoms and resemble sebaceous cysts, fibromas or gummas. Later they may become ulcerated and simulate anthrax. The diagnosis is made by biopsy. The subject of the authors' report was a man aged 37 who one month after recovery from pneumonia developed a chronic bronchitis, changes in the voice and multiple cutaneous nodules over the chest wall. Rapid emaciation, new cutaneous nodules and softening of the early ones followed. The sputum was purulent, hemorrhagic and negative for tubercle bacilli. The patient had no syphilis. Diagnosis of bronchial cancer was confirmed by bronchoscopy, the appearance of left recurrent laryngeal paralysis and of left phrenic paralysis, biopsy of the metastatic nodules and the rapid, fatal course of the disease. Symptoms of peritoneal and intra-abdominal metastasis appeared three weeks before death. The diagnosis was confirmed by a necropsy, which showed generalized cancer of the left lung and mediastinum and a large number of cutaneous and visceral metastases.

*Habitual Dislocation of Shoulder: Study on Nature and Treatment of the Disease, Including Remarks on Traumatic Dislocation. E. Thomsen.—p. 206.

Habitual Dislocation of Shoulder.—Thomsen says that the shoulder and the jaw have a lax joint capsule and are the joints most frequently subject to dislocation. Shoulder dislocations constitute about 50 per cent of all dislocations. It has been stated that 5 per cent of all primary dislocations are likely to become habitual. In about 12 per cent of the cases habitual dislocation is bilateral, but mostly it occurs in the right shoulder (about 66 per cent) and like traumatic dislocation it is most frequent in males. Habitual shoulder dislocation is caused by congenital predisposition but may be provoked by a trauma. The first dislocation in the habitual cases occurs relatively early in life. Statistics indicate that in nearly half of the cases it occurs before the age of 20 and in 90 per cent before the age of 30. In 75 per cent of the cases the recurrences appear before the end of the first year. Gradually the recurrences become more frequent, requiring an ever slighter cause. In between the recurrences there may be subluxations accompanied by pain. The disease may be treated without operation with a bandage holding the arm tied to the body. About seventy operative methods have been reported. The three main types in use are suspension operations, operations on the coracoid process and the Hybbinette-Eden operation. Capsular plication is no longer applied as an independent operation but as a supplement to the two types last mentioned. Thomsen reviews these operative methods on the basis of published reports and his own material of 21 patients treated at the Copenhagen Orthopedic Hospital and the Bispebjerg Hospital and concludes that the Hybbinette-Eden is the most effective method. He favors the Magnus modification of the Hybbinette-Eden method, in which a bone graft is inserted outside the synovial membrane.

Book Notices

Textbook of Abnormal Psychology. By Roy M. Dorcus, Associate Professor of Psychology, University of California at Los Angeles, and G. Wilson Shaffer, Dean of the College of Arts and Sciences, Johns Hopkins University, Baltimore. Third edition. Cloth. Price, \$4. Pp. 547, with 5 illustrations. Baltimore: Williams & Wilkins, 1945.

This is an improved edition of a remarkably good textbook on abnormal psychology. Such books are usually written for college (nonmedical) students, and most of them, though accurate, are insufficiently detailed to give the undergraduate college student a good idea of the behavior of persons who are suffering from a mental disease or who are having abnormal mental experiences. One must perforce think of academic psychology, including the psychology of the abnormal, as bearing the same relationship to psychiatry that college physiology and hygiene bear to general medicine. A knowledge of these basic sciences is useful to the layman in enabling him to comprehend what is going on when mental or physical ailments occur in persons whose health has some bearing on his own adjustment to life. In view of this, basic books on either abnormal psychology or hygiene must be sufficiently complete to serve their purpose yet must stop short of giving the impression to the student that he can practice psychiatry or medicine of even the simplest sort. In the case of abnormal psychology, the material to be discussed is bound to overlap that included in textbooks on psychiatry, yet Dorcus and Shaffer in the present textbook have drawn a very clearcut line. While the researches of the medical profession have by no means been ignored, much space is devoted to experimental studies and investigation from the psychological laboratory and clinic. There is a discussion of basic nonmedical psychology, but a large part of the book is devoted to the description of mental diseases of various sorts and to a general discussion of their treatment. The chapters on treatment are extremely good and emphasize the fact that no psychologist should attempt to give treatment without the supervision of a psychiatrist. There is an extensive bibliography of over eight hundred items which is coordinated with the text. There are some case histories cited as well as a number of worthwhile footnotes. Dorcus and Shaffer have produced an informative, accurate and sensible work, yet it does not transgress fields where the medical man should be the practitioner. It can be highly recommended to graduate students of psychology and to premedical and medical students, and even psychiatrists might find in it items of considerable interest to round out their knowledge of the human mind.

The Story of a Country Medical College: A History of the Clinical School of Medicine and the Vermont Medical College, Woodstock, Vermont, 1827-1856. By Frederick Clayton Waite. Cloth. Price, \$4.50. Pp. 213, with illustrations. Montpelier, Vermont: Vermont Historical Society, 1945.

This interesting and scholarly account of a medical school operating in the small community of Woodstock, Vermont (1827-1856), was written in the belief that "history is more than a mere recital of annals." The book tells the story, not only of a medical school, but of the medical education of the times, an end too seldom achieved in histories of medical schools. In the early nineteenth century about one third of the schools were "country schools," and about one third of the practitioners were graduates of these institutions. At the time, medical education in this country was in its childhood, a few years past the infancy of medical preparation limited to apprentice training. A three year "curriculum" was usual, in which the student attended two sessions (totaling twenty-four weeks) of medical lectures and devoted the remainder of the three calendar years to work with a physician preceptor. There were no graded courses, so that the second didactic session was a repetition of the first, unless the student chose to attend another school, which was common. Laboratory work, hospital experience and full time instructors were virtually nonexistent. Salaries consisted of a division of the balance remaining in the treasury at the close of the year. Dissection was elective, and cadavers were provided by "resurrectionists." The personalities involved, the operation of the school and its place in medical history are set forth in a manner to hold the attention of any one interested in medical education and medical history.

Rypins' Medical Licensure Examinations: Topical Summaries, Questions, and Answers. Fifth edition, revised under the editorial direction of Walter L. Blerring, M.D., F.A.C.P., M.R.C.P., Secretary, Federation of State Medical Boards of the United States, Des Moines, Iowa. With the Collaboration of a Review Panel. Cloth. Price, \$6. Pp. 546. Philadelphia, London & Montreal: J. B. Lippincott Company, 1945.

This book, which is now in its fifth edition, has apparently two major objectives in view. The first is to help dispel the fear with which the average medical graduate approaches the ordeal of the examination for medical licensure, while the second is to aid the candidate in his selection, organization and coordination of medical knowledge already acquired. To carry out this purpose the editorial panel has selected such material as has generally been utilized by the various examining boards. This includes the major subjects of anatomy, physiology, chemistry, bacteriology, pathology, hygiene and preventive medicine, obstetrics and gynecology, medicine, surgery and the addition of a new section on pharmacology. The descriptive material is presented in concise summary form followed at the end of each chapter by typical questions based on a careful analysis of the licensing examinations throughout the United States.

The question and answer form has been abandoned, although the title would seem to imply that this method of presentation is still in use.

The book recognizes that the testing of academic knowledge can best be left in the hands of the medical schools. Accordingly it advocates that licensing boards should limit themselves mainly to the examination of the candidate's ability to apply medical knowledge in clinical practice. This policy does not yet predominate, however, for a great many of the questions used are still academic in nature, requiring little more than the routine memorization of factual data.

There is an excellent discussion on the philosophy of examinations and their importance as an integral part of the program of education and as a measure of knowledge and achievement. Medical students and applicants for licensure will find this volume a convenient, well organized source of reference and a stimulus to further study and review.

Annals of the University of Otago Medical School 1875-1939. By D. W. Carmalt Jones. Cloth. Pp. 286, with 12 illustrations. Wellington, New Zealand: A. H. and A. W. Reed, 1945.

The title "annals" is appropriately selected for this book since it is essentially a compilation of material which might be assembled primarily from annual reports and university catalogues. The author frankly realizes that "the book would have very small appeal outside New Zealand." The University of Otago Medical School is named for the province in which it is located on South Island, one of the two major islands constituting New Zealand. There is a brief account of the country itself and of early medicine on the islands before the establishment of the school in 1875. Most of the book deals with the courageous struggle for faculty, funds and facilities which has characterized the final consummation of an acceptable program of medical education of many medical schools. This task was doubly difficult at Otago, where "it must have been quite exceptional half a century ago for an embryo school, ten thousand miles from England, to secure men of . . . [high] . . . professional standing . . ." for the faculty. Unfortunately, there is little mention of the relationship of medical education to the form of practice in this country, perhaps because the "annals" terminate with the year 1939. It was in 1940 that the Social Security Act was passed, introducing "great changes in the medical practice in the country."

The Outlook for Women in Occupations in the Medical Services: Women Physicians. United States Department of Labor, Women's Bureau, Bulletin 202, Number 7. Paper. Price, 10 cents. Pp. 28, with illustrations. Washington, D. C.: Supl. of Doc., Government Printing Office, 1945.

This pamphlet is an objective compilation of information on the opportunities for women in medicine. The source materials are authoritative. The booklet will be useful to women considering studying medicine and desiring to know the problems they will encounter in so doing.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

POSTURAL TREATMENT OF PULMONARY TUBERCULOSIS

To the Editor:—What is the present opinion on the use of postural treatment in pulmonary tuberculosis? Nathan Sedofsky, Major, M. C., A. U. S.

ANSWER.—Postural rest is not employed as much as formerly, because other procedures have replaced it in many instances. Twenty-five years ago it was generally believed that every patient should have a period of bed rest to give nature an opportunity to control the disease before any other procedure was indicated. Now in large numbers of instances including those of minimal, progressive disease, artificial pneumothorax is instituted almost as soon as the diagnosis is made and the lesion is proved to be active. In many of the unilateral moderately and far advanced cases, extrapleural thoracoplasty is instituted with considerable promptness, and in some cases lobectomy and pneumonectomy are performed without much preliminary treatment.

Some physicians still prefer to prescribe a period of bed rest in all minimal and moderately advanced cases before considering any form of collapse therapy. During this period postural treatment may be used with considerable advantage when the disease is unilateral. In a good many cases in which collapse therapy is indicated and recommended, adhesions have so obliterated the pleural space that satisfactory artificial pneumothorax cannot be instituted. Again, one encounters patients who refuse all forms of collapse therapy. In all such cases postural treatment may be helpful. Even in cases of bilateral pulmonary tuberculosis when one side is not extensively involved and collapse therapy is not indicated, cannot be done or is refused, postural treatment may assist in bringing about sufficient improvement in the more diseased lung so that collapse therapy is indicated or is accepted by the patient.

When postural treatment is instituted, the patient is instructed to lie on the side of the diseased lung as long as possible each day. The time is increased as fast as the position can be tolerated. A small, hard pillow usually is placed beneath the ribs. The lung on the side on which the patient lies undergoes less movement than the opposite lung during respiration, and its aeration is greatly decreased. The heart and other mediastinal structures become displaced toward the recumbent side, the ribs are brought closer together, and when the foot of the bed is slightly elevated the abdominal viscera push the diaphragm upward on this side. All of this results in diminution of the lung volume. The decreased activity of the lung brought about in this manner often promptly results in definite decrease of symptoms, and in due time there is other evidence of improvement of the lung condition.

Postural treatment is valuable also in controlling hemorrhage. Moreover, it prevents blood from being aspirated into the opposite bronchial tree, where it may spread the disease or cause pneumonia. In like manner, even in the absence of hemorrhage, bacilli containing materials from the lesion are prevented from being aspirated into the opposite lung. Always, when artificial pneumothorax is being instituted or any other form of collapse therapy is administered, the patient should lie as much as possible on the involved side to prevent spread of the organisms to the opposite lung.

CANCER IN VETERANS

To the Editor:—Is there any indication in the statistics of the Veterans Administration that veterans are seeking treatment for cancer earlier than formerly in response to efforts to impress them with the vital importance of treatment in the first stages? M.D., New York.

ANSWER.—The most recent report on the cancer service of the Veterans Administration appears to be that on the admissions to the tumor clinic of Hines Veterans Hospital in 1943 (Schrek, R., and Allaben, G. R.: Statistical Analysis of 2,407 Admissions to the Tumor Clinic of Veterans Hospital, Hines, Ill., during 1943, *Cancer Research* 5:539 [Sept.] 1945). This

hospital has 1,800 beds, of which approximately 500 are allocated to the tumor clinic. Of 2,407 patients admitted to the clinic during 1943, 2,222 (including multiple admissions of the same patient) were cancer patients. These admissions are subjected to a careful statistical analysis with respect to geographic, racial and age distributions, deaths and treatment. The table giving types of treatment and percentages of deaths of patients with various types of tumor does not give information about the duration and extent of the disease in the treated patients or about their history before admission. The report does not present any facts on which to base an affirmative answer to the question, and it does not convey the impression that the Veterans Administration, at least up to and including 1943, has been supporting any formal educational campaign to promote early diagnosis and prompt treatment of cancer in its beneficiaries.

THE LIVER IN DIABETES

To the Editor:—In the June 4, 1945 issue of *Newsweek* there was a short article on diabetes. The following medical research men were named: Dr. Morton S. Biskind, Dr. Herbert Schreier, Dr. Samuel Siskin, Dr. Oliver H. Goebler and Dr. Walter E. Cieszkowski. It seems these men are unanimous in their findings that the liver is the most important factor in the treatment of diabetes. The article states that vitamin B complex, given orally or intramuscularly for diabetic conditions, results in a "striking improvement in health and well being." It also states that "for best results, however, the treatment must include intensive and unusual nutritional therapy." Will you send me particulars on this? Does vitamin B complex mean thiamine? What, exactly, is meant by "intensive and unusual nutritional therapy" in regard to this treatment of diabetes? M. E. Morr, Dietitian, Vetslaro, B. C.

ANSWER.—The article in *Newsweek* for June 4 emphasizes the role of the liver in diabetes. It has long been known that the liver is of fundamental importance in carbohydrate metabolism. Its chief function is to control the level of the blood sugar. Such action is secondary to the endocrine influences of the body, chiefly those of the pancreas (insulin). In discussing these various factors Dr. Samuel Siskin (*J. Clin. Endocrinol.* 4:75 [Feb.] 1944) says "It must be emphasized that none of these considerations minimizes the importance of insulin in therapy or suggests that any other efficacious agent is known at the present time."

In the treatment of diabetes, insulin is of prime importance. However, the effects of both vitamin B complex and thiamine (the latter is, of course, only part of the complex) have been investigated in diabetes. For adequately nourished diabetic patients whose diabetes is well controlled these substances are of no use in altering the course of the disease or reducing the insulin dosage (Freston, J. M., and Laughlin, Winifred C.: Vitamins and Diabetes, *Proc. Am. Diabetes A.* 2:187, 1942).

Poorly nourished diabetic patients or those whose diabetes is not controlled often have vitamin B deficiency. Since the factors of the vitamin B complex do have a part in carbohydrate metabolism, treatment of such patients by adequate diet, vitamins or both often will result in better utilization of sugar and reduction of the dosage of insulin. The meaning of "intensive and unusual nutritional therapy" mentioned in the question is not known.

X-RAYS FOR HYPERHIDROSIS

To the Editor:—I have a generalized hyperhidrosis and have had all sorts of medical treatment, including x-ray therapy—all to no avail. Six years ago I had a dorsal sympathetic ramiectomy with relief in the upper extremities. My 5 months old daughter has a severe hyperhidrosis of the hands and feet and I have spoken to several competent dermatologists as to the advisability of x-ray therapy. Opinion is divided as to the practicability of this treatment, as it is said that this will require a dose which may impair bony development or damage the skin irreparably. I have been advised to wait until she is adolescent. However, I feel I have been advised to wait until she is adolescent. However, I feel that although x-ray therapy did not help me it will work while my daughter is still young and the skin is possibly more radiosensitive. I feel that, if this condition is allowed to continue, the possibility of cure will diminish. M.D., New Jersey.

ANSWER.—The amount of x-ray therapy needed to control hyperhidrosis of the palms and soles is relatively large. The skin is probably damaged by it. When successful, there is often an abnormal drying and changes more or less characteristic of a radiodermatitis. The latter may not appear until years later. This should be enough to decide against x-ray therapy. The danger of injuring the growth centers of the bones of the hand with this modality as suggested in the query in a 5 months old infant is real. There is no evidence, on the other hand, that the sweat glands of such a young subject are more sensitive to these rays than are those of older persons. Safer treatments are advised, notwithstanding their doubtful benefits.

TRANSCRANIAL REMOVAL OF INTRA- ORBITAL TUMORS

J. GRAFTON LOVE, M.D.
AND
WILLIAM L. BENEDICT, M.D.
ROCHESTER, MINN.

The diagnosis of orbital tumors is at times very difficult and the decision as to the best surgical approach to tumors situated within the orbit is often even more difficult. When there is no question of intracranial extension, tumors in the anterior portion of the orbit can be treated quite satisfactorily by the ophthalmic surgeon through an anterior orbital approach. However, since many posterior orbital tumors have an intracranial component, as pointed out by Dandy¹ in his monograph, since the prime purpose of the surgical treatment of intraorbital tumors is to conserve vision and to have as nearly normal function of the eye as possible, and since the transcranial approach to such tumors through the roof of the orbit gives maximal exposure and direct visualization of the structures within the posterior part of the orbit and permits at the same time the removal of any intracranial extension of the tumor, the neurosurgeon should be responsible for the surgical treatment of such retrobulbar orbital tumors. Nevertheless, cooperation between the ophthalmologist and the neurosurgeon can provide the patient the maximal benefit from treatment. It should require little emphasis that the ophthalmologist must bear the greater part of the burden in determining the treatment in these cases, for he is most likely to see the patient first because of proptosis or visual disturbance, symptoms referable to the eye. There are, of course, diseases other than intraorbital tumors which produce proptosis and visual disturbance, and they must be excluded. Sometimes a period of observation is necessary before the nature of the lesion can be determined. If proptosis increases or vision fails, neurosurgical consultation should be had to attempt to arrive at a diagnosis, since there are many intracranial lesions which produce proptosis and visual loss, even unilaterally.²

Of the surgical approaches to the orbit, the most direct is through the outlet, the anterior opening. The eyelids, the septum orbitale and the eyeball fill the outlet and limit the space for operation under direct

vision within the orbit to the anterior third. A tumor situated in the posterior portion of the orbit,³ such as an encapsulated hemangioma, may be exposed to view by an opening made along the superior orbital rim and exposing the roof of the orbit, but the dissection of such a tumor must be done by touch, as it is practically impossible to retract the tissues sufficiently for a full view of the tumor and its attachments.

Tumors situated in the anterior third of the orbit should be removed by the most direct route or by a route that will cause the least trauma and result in the least loss of function of the eye and eyelids and the least disfigurement. Anatomic conditions determine that course. To reach a tumor in the lacrimal fossa, for example, the surgeon may use the frontal approach either through the upper conjunctival cul-de-sac or through the upper lid beneath the brow to the bony rim of the orbit. The former route calls for a wide canthotomy and bares the cornea to exposure and trauma during the operation. The latter route does not sever any important structure and permits more room for manipulation than the approach through the cul-de-sac. Only the anterior approach need be considered for removal of tumors that are confined to the anterior portion of the orbit, including osteomas, which, as we know, arise outside the orbit within the sinuses and extend into the orbit by a small pedicle.

Another route to the orbital contents is by way of a resection of the lateral wall of the orbit, Krönlein's operation. This has never been a much used operation because the working space obtained by reflecting the bony flap is always disappointing. Even though the bony portion of the reflected wall is entirely removed temporarily, as it may be, little or no more working space is obtained than by the approach through the brow incision.

Krönlein's operation is useful in removal of tumors of the optic nerve without enucleation of the eyeball or in removal of encapsulated tumors situated near the apex of the orbit. For removal of tumors in this region a transcranial approach is usually to be preferred. The choice of approach must, however, at times be determined by a factor other than that of accessibility. If further decompression of the orbit is desired, it is hardly possible to get the required bone resection by Krönlein's method, whereas by the transcranial approach not only can the entire roof of the orbit and the optic canal be removed but the lateral wall can also be resected as far as necessary.

For removal of tumors that are definitely confined to the orbit, even in the posterior third, the frontal or

the Kronlein operation may be entirely adequate, as has been proved many times. However, one seldom can be certain that a tumor known to be in the apical portion of the orbit does not extend beyond the orbital walls, or where its origin may be.

Meningioma is the most frequent of orbital tumors that involve the wall of the orbit and the cranial cavity. Meningioma, or endothelioma, is found in persons of all ages and is particularly malignant in children. It is also probably the most frequent of all tumors found in the posterior portion of the orbit in children less than 15 years of age. Such tumors cannot be removed by either the anterior route or Krönlein's operation but only by the transcranial method.

The transcranial approach, permitting resection of the optic nerve to the chiasm, is the operation of choice in enucleation of eyes for retinoblastoma. While other foci may be present in the central nervous system to account for multiple gliomas, and while metastasis may be present before the retinoblastoma has been detected, the complete removal of the nerve is desirable because

the method best designed to meet the demands of the situation. The transcranial method was employed in 35 cases between Nov. 6, 1933 and Nov. 14, 1944.

SURGICAL TECHNIC

The approach to tumors within the posterior portion of the orbit that are to be removed transcranially is the same as that used by neurosurgeons for the transcranial removal of tumors involving the pituitary gland. Many surgeons vary a little in their technic of elevating a frontal flap, but essentially the steps are as follows:

Through an incision curved upward and forward from in front of the external ear the scalp is dissected free from the underlying temporal fascia and turned forward. The temporal fascia, temporal muscle and pericranium are incised around the margins of the proposed bone flap except at the base in the temporal area where these structures serve as a hinge on which to bend the bone flap downward. The bone flap is then elevated after making multiple burr holes and connecting them

Fig. 1. (Case 27)—a, normal left optic foramen, b, enlarged right optic foramen, c, astrocytoma of right optic nerve removed transcranially. The excision was due to intracranial extension of the tumor.

the tumor is known to spread by direct extension along the optic nerve to invade the brain.

It is difficult to argue that removal of all of the optic nerve rather than merely the intraorbital portion will save more lives. There is some reason for the belief that the tumor extends slowly along the nerve, and there is the possibility that it may be interrupted in the canalicular portion.

As long as there is uncertainty regarding the extent of a tumor in the posterior portion of the orbit, most tumors so situated should be removed by the transcranial route. Recently the transcranial method of approach to the orbit has been made quite safe, and as more surgeons are trained in the necessary technic of head surgery than are ophthalmologists in orbital surgery the better results obtained by the transcranial operations of neurosurgeons become apparent.

Figures taken from the records of the Mayo Clinic show that in the years 1907 to 1944 inclusive there were 2,985 patients who had tumors of the eye or the adnexa or both, of whom 738 (24.7 per cent) had tumors of the orbit. More than thirty-one different kinds of tumors were encountered. Many were primary tumors of the eye and orbit in various stages of development. Operation was performed on a total of 395 by

with a Gigli saw. The dura mater is stripped from the floor of the anterior cranial fossa (which is for all practical purposes the roof of the orbit), and the frontal lobe of the brain, protected by the dura mater, is gently retracted upward and toward the opposite side of the cranium. With the patient receiving drop ether over the end of a Magill intratracheal tube, this is not difficult. The orbital plate is then perforated and removed with rongeurs. It is unnecessary to incise the dura mater if the tumor is entirely intraorbital; if, however, the tumor extends through the optic foramen or the superior orbital fissure, then it is a simple matter to incise the dura mater along the sphenoid ridge in order to expose the entire tumor and effect a complete removal. If the necessity for incising the dura mater is not present, it is better to leave it intact as a protection for the frontal lobe of the brain and as a barrier against bleeding and possible infection. Blood in the subarachnoid spaces will produce meningism and cause the patient distress and the surgeon, sometimes, unnecessary concern.⁵ At times in effecting the complete removal of an intraorbital tumor the ethmoid air cells

4. Some few surgeons still use the transphenoid approach.
5. Hamme, E. M., Jr.: Reaction of the Meninges to Blood, *Arch Neurol & Psychiat.* 52: 505-514 (Dec.) 1944.

may be opened and thus the danger of infection is a real one. In 1 of our cases there was gross pus within the orbital tumor. Yet, in spite of this, we have not lost a single patient from infection.

We have not encountered bilateral orbital tumors which have required transcranial removal. We have had several cases of ghoma of the optic chiasm with

the supraorbital ridges. The portion of frontal bone thus exposed is removed and kept wrapped in a sterile towel wet with saline solution until it is to be replaced at the end of the operation. The dura mater is stripped from the crista galli and cribriform plate of the ethmoid and from the orbital roofs, thus giving exposure of the entire anterior cranial fossa.

Intraorbital Tumors Removed Transcranially

* Previously reported.

extension of the lesion along both optic nerves into the orbits, but because of the fact that removal of such a tumor would result in total immediate and permanent blindness we have been reluctant to remove such tumors. Possibly this is a mistake, but the results of conservative treatment seem to justify our present methods.

Bilateral orbital tumors can be removed in one stage by utilization of the coronal or Souttar flap. The incision goes across the head, paralleling the coronal suture. Then the scalp, pericranium, temporal fascia and muscles anterior to the incision are displaced forward to

MATRIM

As a result of the observations of the ophthalmologists, radiologists, neurologists, neurosurgeons and pathologists at the clinic and a study of a group of cases in which intraorbital tumors have been removed following the elevation of a frontal skull flap and the removal of a part of the orbital roof, our ideas for the successful handling of tumors within the orbit have become well crystallized.

In this paper, which of necessity cannot be a monograph on orbital tumors, we have excluded all tumors

that have arisen on or in the face and invaded the orbit secondarily. We have excluded tumors of the maxillary antrum that have secondarily invaded the orbit. Likewise we have excluded from this report many tumors, meningiomas, gliomas and lymphoblastomas which were mainly or largely (as far as size was concerned) intra-

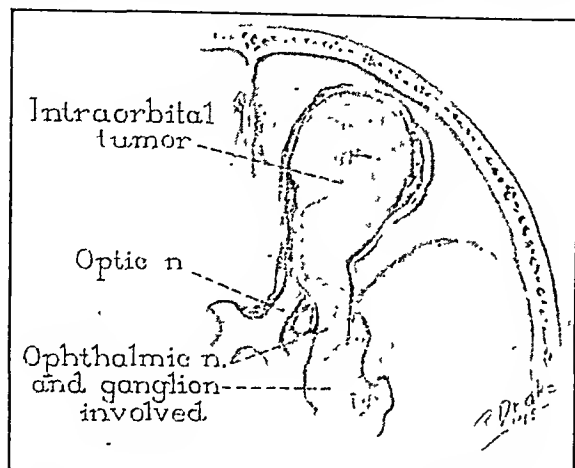

Fig. 2 (case 30).—Neurofibroma which involved the intraorbital portion of the ophthalmic nerve and extended intracranially to involve the gasserian ganglion and all three peripheral branches.

cranial with minimal intraorbital extension. What is even more important, we have excluded several hundred tumors which were located in the anterior position of the orbit and which were operated on by the ophthalmic surgeons.

ANALYSIS OF DATA ON ORBITAL TUMORS REMOVED TRANSCRANIALY

In a group of 35 consecutive cases⁶ in which intraorbital tumors were approached through the roof of the orbit after frontal craniotomy had been performed, it was found that 22 patients were female and 13 were male. The average age of the patients at the time of operation was 27.5 years, the oldest patient being a man aged 53 and the youngest a boy aged 2 months.

Fig. 3 (case 25).—Astrocytoma of right optic nerve showing intracranial extension which could be removed only by means of a transcranial approach.

The tumor occurred in the right orbit in 18 cases and in the left in 17 cases. There was no case of removal of bilateral intraorbital tumors in this series. Proptosis

or prominence of the eye on the side of involvement was the most important symptom of which complaint was made and the most frequently detected sign. Thirty-three patients had proptosis or exophthalmos (the only exceptions being cases 10 and 16, table), and in 20 cases it was the first symptom that the patient had noticed. Failing vision and headaches are late symptoms, and headaches usually mean extension of the tumor beyond the confines of the orbit.

Roentgenologic examination of the head and orbits, including the optic foramina, is a most valuable part of the investigation of the patient suspected of having an intraorbital tumor (fig. 1). In 27 of the 35 cases here analyzed the roentgenologist gave definite help in establishing the diagnosis by reporting changes in the configuration of the orbit, alterations in the size and shape of the optic foramina, the presence of erosion or formation of osteoma involving the walls of the orbit or the presence of calcium (signifying old hemorrhage) within the orbit.

When the tumors were uncovered and removed, it was found that in 22 cases the tumor was entirely within the orbit, whereas in 10 cases there was intracranial extension. In the 3 remaining cases there was extension into adjacent bone or into the frontal sinus and in 1 case even into the nose.

Fig. 4 (case 25).—Astrocytoma of optic nerve removed transcranially.

The pathologic character of the lesions varied a great deal and can be determined for each case by referring to the table.⁷ There was only one death in the series and this case, which is reported in detail, was most unusual.

CASE 30.—A boy aged 1½ years was observed by the parents, when the child was 3 months of age, to have a "bump" in the right frontotemporal region, although they had noted shortly after birth that the right upper eyelid was thickened and larger than the left.

Examination revealed considerable proptosis of the right eye, but accurate exophthalmometer reading was impossible because of poor cooperation. There was a soft nodular puffiness throughout the right lid, at the outer portion of the fissure and extending into the temporal region. At the posterior part of this region was a small, irregular, hard tumefaction, which was considered bony. Fundus examination was not done. Roentgenologic examination revealed what happened to be an anomaly of development of the skull in the region of the right orbit.

On June 24, 1944 right transfrontal craniotomy was performed with right orbital decompression and resection of an intra-

6. Adson, Craig; Uihlein and Kloos gave permission to have their cases included. In 21 of the cases operation was performed by one of us (Love).

orbital tumor and subtotal resection of the intracranial portion of the same tumor. When the bone flap was turned down there was found an osteoma of the outer third of the roof of the right orbit. The bony mass which had been felt in the temporal area prior to operation was an outward bulging of the squamous portion of the temporal bone. When the roof of the orbit, including the osteoma, had been removed the periorbital appeared abnormally thin. When it was incised, a very firm tumor, extending from the anterior portion of the orbit to the superior orbital fissure, was uncovered. It felt very fibrous and suggested a neurofibroma. A specimen of its wall, submitted for fresh frozen section diagnosis, was reported as definitely neoplastic. Since no other abnormal mass in the orbit could be felt, the tumor was divided and nerve bundles were found in it. The nerve was larger than any nerve normally within the orbit, including the optic nerve, and because of its position it seemed unlikely that it could be the optic nerve. The anterior portion of the neoplastic nerve was dissected from the anterior portion of the orbit and removed. Then the nerve was dissected backward to the superior orbital fissure. The dura along the wing of the sphenoid was then opened to be sure of the exact location of the optic nerve. It was found at least 1.5 cm. below the level of, and mesial to, the aforementioned neoplastic nerve. It was normal in color and size.

Fig. 5 (case 22).—Size and position of intraorbital angioma that was removed trans-cranially.

The dura mater along the tip of the temporal lobe was then incised. Much to our surprise, it was about ten times as thick as it should have been and very vascular, suggesting a sessile type of meningioma. The involved dura was incised toward the midline below and the incision was extended upward over the temporal lobe and the inferior portion of the frontal lobe to join with the previously made incision along the wing of the sphenoid. Practically all of this dura was involved in this process. Then the neoplastic nerve and the involved dura were grasped and dissection was carried down to the cavernous sinus, at which point a stick tie of silk was placed around the nerve, which now was proved to be the ophthalmic division of the fifth nerve. The involved dura and neoplastic nerve were resected. The foramen rotundum and foramen ovale were identified, and it appeared that the branches of the fifth nerve going through these foramina were likewise involved (fig. 2). It was impossible to free the dura mater from the three branches of the gasserian ganglion and from the ganglion itself. It seemed that in order to resect the ganglion and remove it with all three branches it would be necessary to open the cavernous sinus. Since the patient had already been under anesthesia for a long time and since the tumor was reported as benign, it did not seem advisable to attempt complete removal of the ganglion and the maxillary and mandibular divisions. All bleeding was under control. The dural defect was covered with animal membrane. The bone flap was tied in place with two pieces of wire. The muscle, fascia and galea were closed

with continuous number 0 chromic catgut and the skin was closed with a continuous cotton suture.

The pathologist reported the tumor as a fibrous neurofibroma. In spite of the fact that the child was given a transfusion during the operation and again that evening and that the postoperative course was fairly good for eighteen hours, at the end of that period the patient suddenly had a generalized convulsion, which was controlled by aspirating cerebrospinal fluid through the cra-

Fig. 6 (case 22).—Appearance eleven days after transcranial removal of intraorbital angioma (see fig. 5).

nial flap. Hyperthermia developed and could not be controlled. The patient died approximately twenty-four hours after operation.

Figures 3 to 12 inclusive illustrate various cases in which intraorbital tumors were removed by the transcranial approach.

Short summaries of 4 cases illustrative of the problems involved in the diagnosis and treatment of tumors of the orbit follow:

Case 33.—A boy was the youngest patient in our series of intraorbital tumors. At the time of operation he was only 2 months of age, and naturally the examination was not as easy as it would have been if he had been an adult.

The patient was referred to the clinic because of severe proptosis of the right eye since birth. The mother was under the impression that the abnormal prominence of the right eye had not increased. On examination the right eye was found to be pushed forward and temporalward. Because of lack of

Fig. 7 (case 23).—Proptosis of right eye due to osteitis fibrosa cystica involving the roof of the orbit.

Fig. 8 (case 23).—Bone cyst pushing the eyeball forward in the orbit.

cooperation the exophthalmometer could not be used, but it was estimated that the exophthalmos was at least 10 mm. and probably more. It was observed that when the child was asleep the right eye was partially open (fig. 13). A nonpulsating mass could be palpated on the nasal side of the eyeball. The eye was freely movable but could be pressed backward into the orbit only slightly. The pupil was well dilated and the

fundus was easily seen. No choking of the disk was present and there was no edema of the retina. Roentgenologic examination of the head revealed an expanding lesion of the right orbit, which had caused enlargement of the orbit and orbital fissure.

Right transfrontal craniotomy was performed with the patient under ether anesthesia. Because of the youth of the patient

Fig. 9 (case 23).—Lateral view of head showing cyst in roof of right orbit.

no burr holes were necessary. After the scalp had been reflected over the right frontal region, most of the right frontal bone was freed from the underlying dura mater and the longitudinal sinus. The flap was narrowed at its base just above

Fig. 10 (case 23).—Appearance twelve days after removal of orbital tumor by transcranial approach (see figs. 7, 8 and 9).

Fig. 11 (case 23).—Appearance twelve days after intraorbital approach.

uncovered. The tumor was removed piecemeal with a curet and sucker. One portion of the tumor was attached to a small nerve at the junction of the mesial and posterior walls of the orbit. This nerve was silver clipped and divided in order to remove the attached tumor.

After removal of the tumor there was a large cavity within the posterior mesial portion of the orbit. The dura mater was not opened at any time. The optic nerve was not exposed. The superior orbital fissure, which was enlarged in the roentgenogram, was not visualized. The bone flap was replaced and anchored in position with a few interrupted silk sutures. The scalp was replaced and closed hurriedly with through-and-through continuous silk sutures because the child's condition at this point was critical in spite of the fact that we had taken the precaution of placing a needle in the vein in the left arm and administration of fluids had been started before the operation was begun. The tumor was reported as a slow growing cellular neoplasm either from a nerve sheath or from the meninges. The note was made that it was not a typical neuroma or a typical meningioma but a fibrosarcoma. A hematoma developed postoperatively between the scalp and the bone flap and this became infected. With the subcutaneous use of penicillin and application of sterile warm moist packs to the scalp the infection

Fig. 12 (case 10).—Appearance three and a half months after transcranial removal of intraorbital meningioma. Six and a half years later she reported "no further trouble" with her eye.

was controlled and the patient was able to return home approximately six weeks after operation (fig. 14). Subsequently he was reported in good condition.

CASE 12.—An intradiploic, intracranial and intraorbital epidermoid tumor was removed through a right transfrontal craniotomy. A woman aged 30 was referred to one of us (Benedict) because of pain and proptosis of the right eye, which had been called to her attention by her sister six months prior to her coming to the clinic. It was impossible from the history to determine whether the symptoms had been sudden or gradual in onset.

Examination revealed proptosis of 7 mm. in the right eye. The lids protected the eye well. On palpation there was considerable tenderness on pressure at the inner third of the supraorbital margin with the sensation of fullness. Nothing could be expressed from the tear sac. Extraocular movements were slightly impaired in all directions. There was alternating exotropia. The pupils and pupillary reflexes were normal. Tactile tension was within normal limits. The anterior cham-

bers were of normal depth. The irises were normal. The lenses and the vitreous were clear. The fields of vision were normal. The fundus of the right eye showed a disk of good color with blurring of the upper and lower poles and nasal margin with what appeared to be early edema extending into the nasal portion of the retina. The veins were mildly engorged. The macular regions showed an increased light reflex. No hemorrhages nor exudates were seen. Examination of the left fundus revealed a disk of good color with slight blurring of the upper and nasal margins suggesting early edema. The rest of the fundus was normal. The vision was 6/5 in each eye.

Roentgenologic examination of the head revealed a destruction of the posterior inferior portion of the right orbit and wing of the sphenoid extending laterally where there was irregular erosion of the inner table of the lateral portion of the frontal bone and contiguous portion of the sphenoid and parietal bones. The changes in the bones were interpreted as those of pressure secondary to a benign type of tumor, probably an atypical epidermoid.

A right frontotemporal type of craniotomy was performed. A large cystic epidermoid tumor was evacuated and the capsule

Fig. 13 (case 33).—Two months old child with tumor in right orbit. Note inability to cover globe with eyelids.

of the tumor, which was partially intradiploic but also intracranial and intraorbital, was removed. The roof of the orbit had been completely and cleanly eroded by the tumor and it was easy to follow the continuation of the intracranial dura mater along the right optic nerve to form the periorbital. It was not necessary to incise the dura mater or the periorbital in this case, as the capsule of the tumor was easily stripped from these structures.⁸

Occasionally the nose and throat surgeon is the first to encounter a brain tumor or an intraorbital tumor when he attempts to remove a "polyp" from the ear or from the nose. Meningiomas fairly often extend into the external auditory canal and into the frontal sinuses or even into the nose itself. In the following case an intraorbital tumor was first attacked within the nose by a nose and throat surgeon:

CASE 17.—A man aged 30 had suffered from nasal obstructive symptoms for two years and had had some discharge from the right nostril for one and a half years. He had known of a growth in the right nostril and of unusual prominence of the right eye for one year. For two months there had been some blurring of vision. The patient stated that two months

before coming to the clinic he had had an intranasal operation for the removal of a mass the microscopic examination of which was reported as showing either a psammoma or a psammosarcoma. It was after this operation that the patient began to note blurring of vision.

The patient's general physical appearance was not remarkable except for rather severe proptosis of the right eye. The vision

Fig. 14 (case 33).—Post-operative appearance. Lids now cover the eyeball, since proptosis has been relieved by removal of tumor.

was 14/21 in each eye. Pupils, reflexes and fields were normal. Although there was 4 mm. of proptosis in the right eye, no abnormal mass could be palpated within the orbit. The extraocular muscular functions were normal. Examination of the fundi revealed structurally full disks of good color and definition. The retinal veins were relatively full. Examination of the ears, nose and throat

revealed a slight retraction of both ear drums and slight conduction deafness on the right side. The pharynx was injected and the tonsils were red. There was a scar on the right side of the nose and there was a firm nonulcerating mass appearing in the right middle meatus. Roentgenologic examination of the skull and accessory sinuses revealed a large soft tissue mass in the frontal sinuses and extending down into the frontoethmoid region. There were decalcification and posterior expansion of the posterior wall of the frontal sinuses. These findings suggested a benign tumor, probably a large mucocoele. The tissue removed elsewhere was

Fig. 16 (case 21).—Boy aged 3 years who had had increasing prominence of left eye for three weeks.

available for examination. Our pathologist reported that it was a dural endothelioma containing numerous psammoma bodies.

In view of the physical findings and the report of a tumor of the psammoma type having been found in the nose before the patient came to the clinic, we made a diagnosis of an intracranial meningioma with intraorbital and intranasal exten-

8. Love, J. G., and Kernohan, J. W.: Dermoid and Epidermoid Tumors (Cholesteatomas) of Central Nervous System, J. A. M. A. 107:1876, 1932 (Dec. 5) 1936.

sion and advised right transfrontal craniotomy for removal of the tumor. When the bone flap had been elevated and the dura mater was being elevated from the roof of the orbit, it was noted that the roof of the right orbit bulged within the cranium and was parchment thin in some areas and completely destroyed in other areas. The nasal half of the roof of the orbit was most involved. With a punch, a gallbladder scoop

Fig. 17 (case 21).—Astrocytoma of left optic nerve, showing intra-cranial extension, which could be removed only by means of a transcranial approach.

and pituitary forceps, a large amount of tumor was easily removed. When the tumor within the orbit was removed, a large amount of tumor could be seen in the frontal sinus and downward into the nose. As the tumor was being removed, pus was encountered in the mesial half of the orbit. About $\frac{1}{2}$ teaspoon (2 cc.) of pus was removed. A culture of the pus was taken and the wound was swabbed thoroughly with tincture of mercuric iodine. All of the tumor grossly was removed. It was not necessary to open the dura mater at any time. This, we considered, was very fortunate in view of the finding of pus at the operative site. A Penrose cigaret drain was left within the cavity from which the tumor had been removed and was brought out of the incision laterally. The incision was closed in layers in the usual fashion. The tumor was reported by the pathologist as being a meningioma with psammoma bodies. Subsequent report on the culture of pus taken at the time of operation showed no growth of organisms. The patient's convalescence was entirely uneventful. He was dis-

Fig. 18 (case 21).—Astrocytoma of optic nerve, removed transcranially. Patient is well and going to school two and a half years after removal of tumor.

missed from the hospital on the eighth postoperative day, at which time his wound was well healed. He was allowed to return home on the twelfth day after operation (fig. 15).

The importance of maintaining an intact dura mater when removing intraorbital tumors transcranially is emphasized by case 17, since the pus was found within the tumor and because it was necessary to enter the frontal sinus and the nose (a potentially infected region) in order to effect a complete removal of this tumor.

CASE 21.—A boy aged 3 years was referred to the clinic because of increasing prominence of the left eye, which had been noted only three weeks prior to registration. Aside from the proptosis, the child was entirely asymptomatic.

Examination revealed 2 mm. of proptosis of the left eye (fig. 16). The pupils were equal and reacted normally to light. There was edema of the right optic disk of 1 to 2 diopters and of the left disk of 5 diopters.⁹ Roentgenologic examination of the head gave negative results. Left transfrontal craniotomy for a tumor of the left optic nerve was advised and carried out. The roof of the left orbit was very thin, particularly posteriorly toward the apex and over the optic foramen. The periorbita was not discolored and it was impossible to feel the tumor with a finger. The dura mater was incised along the lesser wing of the sphenoid bone in order to expose both optic nerves and the chiasm. When the frontal lobe was elevated from the chiasm, a tumor of the left optic nerve was detected. About 4 to 6 mm. of the tumor could be seen within the cranium; that is, proximal to the left optic foramen. When this mass was traced into the orbit the bulk of the tumor was found to be intraorbital. The optic nerve was silver clipped just distal to the chiasm where it appeared normal, and then the nerve and tumor mass were freed up to the globe. A silver clip was placed snugly against the sclera and the nerve was divided proximal to the silver clip; that is, toward the chiasm. The ophthalmic artery was not identified as such but there was a band of tissue, which was very dense and still held the tumor in place. This was silver clipped and divided, whereupon the

Fig. 19 (case 21).—Appearance of patient sixteen days after removal of astrocytoma of left optic nerve.

entire tumor with a portion of the optic nerve, which appeared normal, was lifted from its bed (fig. 17). There was no bleeding. The incision was closed in the usual manner without drainage. The tumor was reported by the pathologist as being 3 cm. in length, the diameter being 8 mm. at one end, 12 mm. at the other end and 3 cm. in the middle (fig. 18). Microscopically it was an atypical astrocytoma.

The patient's convalescence was uneventful. He was dismissed from the hospital on the eleventh postoperative day and from the care of the clinic on the seventeenth day after operation (fig. 19). At the time of the latest report, two and a half years after operation, he was attending kindergarten and "getting along fine" according to his mother.

SUMMARY

In a consecutive series of 35 cases of intraorbital tumors the transcranial approach through the roof of the orbit afforded excellent visualization of the pathologic growth and the important structures within the orbit and permitted removal of tumors which could not otherwise have been removed. There was only one death in the series, and the results generally have been good.

CONCLUSIONS

This paper further emphasizes the comment made by Adson and one of us (Benedict)¹⁰ in their report of a case (case 1 of this paper) in which a hemangioendothelioma of the orbit was removed through a transcranial approach; namely, "The case with which the hemangioendothelioma was removed suggests many possibilities for the transcranial approach to vascular and neoplastic lesions situated in the retrobulbar space of the orbit."

⁹ The edema of the right optic disk never was explained satisfactorily.

Laboratory¹ and clinical² studies have shown that penicillin is highly effective against the hemolytic streptococcus. It is more active than sulfonamides in protecting mice against lethal infections with this organism.³ There are also a number of reports of hemolytic streptococcal infections which resisted sulfonamide therapy but responded well to penicillin.⁴ Such observations and the lack of toxicity of penicillin have made it the treatment of choice in severe hemolytic streptococcal infections.

Direct comparisons of sulfonamide and penicillin therapy in hemolytic streptococcal infections are included in the reports already mentioned. In addition, Plummer and his co-workers⁵ found that hemolytic streptococci could no longer be found in the majority of throat cultures taken from patients with pharyngitis or tonsillitis after forty-eight hours or more of intramuscular treatment with 15,000 units of penicillin every four hours. The organisms frequently reappeared and symptoms relapsed, if the treatment was carried out for less than six days. Sulfadiazine, on the other hand, reduced the number of organisms in the cultures while the treatment was being given, but they were again found in large numbers after that treatment was stopped. Similar

findings with respect to sulfadiazine were also noted by others.⁶

In this paper are reported the results of bacteriologic studies of four similar but small groups of cases of scarlet fever treated: (A) without sulfonamides or antibiotics, (B) with penicillin intramuscularly, (C) with sulfadiazine orally and (D) by spraying the nose and throat with penicillin solution. There were only 9 patients in each group, but the differences observed were sufficiently striking to warrant this report.

PATIENTS, MATERIALS AND METHODS

The patients studied were admitted to the South Department⁷ of the Boston City Hospital between January and May 1945. They all had the typical clinical picture of scarlet fever without septic complications; none had received any form of specific therapy before entry and all were old enough to cooperate with the methods of treatment and study. They were divided more or less in rotation. Although it was hoped to obtain groups which were of equal severity and comparable in other respects, the group treated with intra-

muscular penicillin included more patients who were moderately or severely ill and also more of the older children. The distribution of cases according to age, duration of symptoms and rash at the time of entry and the number who previously had tonsillectomy are listed in the accompanying table.

The treatment employed was as follows: Group A, no sulfonamides or penicillin. One patient, A1, was given 70 cc. of scarlet fever convalescent serum on the second day because of pronounced toxicity. Group B, 10,000 units of penicillin intramuscularly every three hours, except B5, who weighed more than 100 pounds (45.4 Kg.) and was given doses of 15,000 units. Group C, sulfadiazine 0.06 Gm. per pound per day, given in six doses plus an initial dose which was two thirds of the daily dose. Group D, a solution containing 1,000 units of penicillin per cubic centimeter in isotonic solution of sodium chloride and five sprays from a De Vilbiss atomizer given into each nostril and a similar number into the posterior pharynx. Patients D1 and D2 received this treatment only four times a day, shortly after each meal and at bed time, a total of 100,000 units

being given; the others in this group were sprayed every four hours day and night and each received a total of approximately 200,000 units. The treatment in groups B, C and D was begun within a few hours after entry and was continued for seven full days. All gargles and nose drops were eliminated from the routine supportive therapy in every case.

Cultures from the nose and throat were taken of every patient on admission, twenty-four hours after treatment was begun, two or three more times during the therapy and twice weekly thereafter until the day of discharge. A pair of cotton swabs was swept five or six times across the posterior pharynx and over each tonsillar fossa, and separate single swabs were rotated in each nostril. The nasal and pharyngeal swabs were streaked, soon after they were taken, on separate agar plates containing 10 per cent horse blood. Substreaks were made serially over each of the four quadrants of the plate in order to obtain a rough quantitation of numbers of colonies that developed. In group D about half of the cultures were taken between one and two hours after spraying, while the remainder were obtained less than one hour before the time of spraying.

After twenty-four hours' incubation, roughly quantitative estimations (0 to 4+) were made of the growth of colonies of beta hemolytic streptococcus, *Staphylococcus aureus*, alpha hemolytic streptococcus, pneumococcus and *Hemophilus hemolyticus*. Identification was made from colony morphology and from stained smears.⁸ Subcultures of beta hemolytic streptococci were further classified according to the Lancefield groups, and those of group A were typed by agglutination and the types or representative strains were checked by the precipitin method.⁹ The hemolytic and plasma coagulating properties of strains of *Staphylococcus aureus* were noted. Pneumococci were typed by the Neufeld method. When transparent hemolytic colonies appeared in large numbers, ten such colonies were picked at random. Stained smears were examined, and if they all proved to be gram negative bacilli they were classified as *Hemophilus hemolyticus* and the remainder were assumed to be the same organism. The group A streptococci were all tested for sensitivity to penicillin by the method of Rammelkamp and Maxon.¹⁰

No special attempt was made to protect the patients from cross infections. Patients were admitted to open wards containing four or six beds each, with nurses each attending patients in more than one room. When they were allowed out of bed, the patients from the various rooms mixed freely and played together. Only those who developed other contagious diseases were isolated.

All of the cultures were made by the same observer, who made detailed clinical notations at the time. Routine blood and urine examinations were also done at frequent intervals.

RESULTS

Persistence of Hemolytic Streptococcus.—The results of the pharyngeal and nasal cultures in each of patients are shown graphically in charts 1 and 2, respectively. Only the findings with respect to hemolytic streptococci are shown in these charts.

Pharyngeal cultures were positive for hemolytic streptococcus on entry in all but 2 of the patients, and in both of them moderate numbers of these organisms were found in the cultures taken on the following day. All of the strains obtained from these original cultures were Lancefield group A strains: fifteen were type 2, four were type 4, three each were type 11 and type 22, two were type 10, there was one strain each of types 1, 17, 18, 19, 23 and 26, and one strain showed cross reactions with types 17, 19 and 23 antisera. Two strains could not be classified with the available serums (types 1 to 30).

Nasal cultures taken on admission were positive for hemolytic streptococcus in only 11 patients, but 9 others had them in subsequent cultures taken during the first six days. Most of the latter were found on the day after entry. The types obtained from the nose corresponded to those found in the throat in every instance. The results of subsequent cultures varied widely in the four groups, each of which will therefore be considered separately.

GROUP A (no sulfonamide or penicillin). The pharyngeal cultures in this group showed minor fluctuations in the numbers of beta hemolytic streptococci, but the original strain was found in every instance. Persistently negative cultures were obtained before discharge in only 4 of the 9 patients in this group. The first negative culture in these 4 cases was obtained on the 15th, 19th, 28th and 29th days, respectively.

The nasal culture showed hemolytic streptococci on admission in only 1 patient in this group, but these organisms appeared in cultures of all the other 8 patients from one to nineteen days later. They were obtained intermittently in 2 cases and during a brief period only in 2 others. There were considerable fluctuations in the numbers of organisms found in the cultures obtained on different days in the same patients. The same type was isolated in each case from all of the nasal and pharyngeal cultures except in A4, in which type 1 was isolated from the nose after the first week, while type 2 was found in the throat.

GROUP B (intramuscular penicillin). The most striking effects of treatment were noted in this group. Throat cultures became and remained free of the original types of hemolytic streptococci after twenty-four hours in 1 case and in forty-eight hours in 6 others. In the 2 remaining patients the hemolytic streptococci persisted with temporary lapses until one week after the treatment was stopped. In 3 cases of this group hemolytic streptococci of types different from the original one appeared in the throat cultures near the end of the period of observation from one to five weeks after the penicillin treatment was stopped.

All the nasal cultures became or remained free of hemolytic streptococci throughout the period of treatment except in 1 case, in which they were recovered during the first two days. Strains of new types appeared in the nasal cultures of 2 patients and corresponded to those found in their throats at that time.

GROUP C (oral sulfadiazine). The results in this group were similar to those found in sulfonamide-treated cases of hemolytic streptococcal infections by others.¹¹ Hemolytic streptococci were reduced in num-

Watson, Rothbard and Swift.¹² Plummer, Dierschner, Warren, Rogliano and Sloan.¹³ Commission on Acute Respiratory Diseases.¹⁴ Rubenstein and Foley.¹⁵

Alpha hemolytic streptococci were found in moderate or large numbers in throat cultures throughout most of the period of observation in almost all of the cases. In most of those treated with penicillin, either intramuscularly or by spray, they disappeared from the cultures during the last two or three days of treatment, only to reappear later in larger numbers. Hemophilus hemolyticus, which is somewhat similar to the staphylococcus

in its susceptibility to penicillin,¹² appeared only sporadically in the nose and throat cultures. Interestingly enough, this organism occurred in moderate numbers during the treatment period in 5 of those who received penicillin intramuscularly and in 1 who received it by spray. It was not recovered from any of the cultures in the sulfadiazine treated cases.

CLINICAL RESULTS

The clinical results need only to be mentioned briefly, since the numbers of cases were too few to permit any definite comparisons or conclusions. The average duration of fever, rash and acute toxicity was essentially

average would have been even shorter in group B were it not for the regulations which required all scarlet fever patients to be kept for a minimum of twenty-one days. In addition, 1 of the patients in group B was kept in the hospital for five weeks longer in an attempt to cure a chronic otitis media from which only *Proteus vulgaris* but no hemolytic streptococci was cultured. These findings only corroborate the general clinical impression of a more complete and rapid clinical cure in the cases treated with intramuscular penicillin.

COMMENT

The most striking result of the present study is the demonstration that penicillin given in therapeutic doses intramuscularly is effective in rapidly eliminating hemolytic streptococci from the nose and throat of patients with scarlet fever. When given by spray alone, in the manner used in this study, a concentrated solution of penicillin, like tyrothrycin,¹³ was not effective except possibly in suppressing these organisms in the nose temporarily. Some workers, however, have reported favorable results with local applications of penicillin in the nose and throat in clearing diphtheria carriers.¹⁴ When the intramuscular penicillin treatment was continued for seven days, the original strains of streptococci did not return in the nose and throat after the treatment was stopped. Plummer and his associates⁶ observed a similar effect in cases of streptococcal pharyngitis and tonsillitis. They noted that when penicillin was discontinued the hemolytic streptococci tended to return gradually in the nasopharyngeal cultures, and the frequency of their reappearance was inversely proportional to the length of time the penicillin was administered. Clinical relapses in their cases also occurred if the treatment was carried out for less than six days, and 1 of their patients developed streptococcal sinusitis and pneumonia later, after treatment for six days. In small groups of cases of rheumatic fever treated with intravenous or intramuscular penicillin for longer periods and with larger doses, hemolytic streptococci could not be found in nasopharyngeal cultures after the treatment was started.¹⁵ In similar cases treated for shorter periods, the streptococci often recurred after the treatment was stopped.¹⁶

The experiences with the use of sulfadiazine given orally in full therapeutic doses for seven days were similar to those reported by others in cases of simple pharyngitis.¹⁷ In a recent study of an explosive outbreak of hemolytic streptococcal sore throats in which alternate patients received full doses of sulfadiazine for five days, the percentage of positive cultures for hemolytic streptococci during the time of treatment was about one half of that among the controls that were treated only symptomatically. After sulfadiazine was discontinued, the percentage of positive cultures among the treated and control cases was practically identical.^{17a}

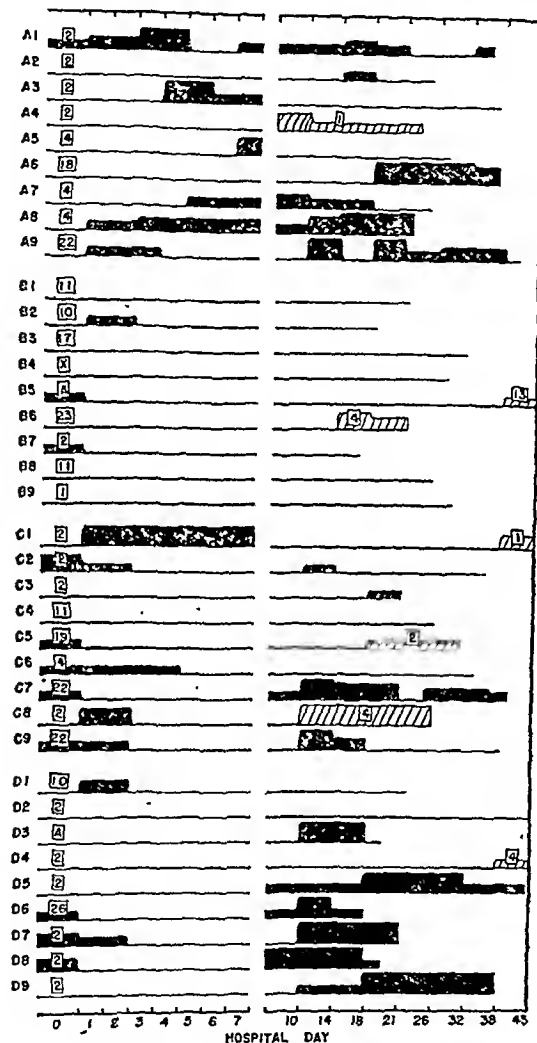

Chart 2.—Hemolytic streptococci in nasal cultures. See notes under chart 1.

the same in all four groups. Sore throat disappeared rapidly and did not recur in the cases treated with intramuscular penicillin, whereas symptoms and signs of pharyngitis persisted in some of those in each of the other groups. Septic complications did not occur in any of the former; whereas rhinitis, catarrhal otitis media and nonsuppurative cervical adenitis each developed in 1 to 4 patients of group A, C and D, and 1 of those in group A and in group C developed a paronychia. The average hospital stay in the cases treated with intramuscular penicillin was twenty-nine days, as compared with thirty-seven days for all of the other groups. This

The clinical results also suggest that penicillin given intramuscularly during and for several days after the eruptive stage may minimize or even eliminate the late septic complications. The majority of these complications occur after the second week of illness and have been shown by some workers to be due to organisms acquired by cross infection.¹⁸ These should be preventable by adequately treating all of the patients and thus eliminating the sources of cross infections. Furthermore, should these findings be corroborated on a large scale, the present requirement of isolation for scarlet fever patients for three or four weeks would become unnecessary, and patients could be discharged after eight or ten days without danger of giving rise to secondary cases or of cases returning with complications. Such a reduction in the period of hospitalization and the elimination of the case-carriers in military installations might well justify the longer period of intensive treatment even in cases of simple pharyngitis and tonsillitis in which treatment for more than one or two days might otherwise seem superfluous.

Further developments in penicillin therapy may simplify the administration of such a program. Thus the use of penicillin X may result in the reduction in the frequency with which the doses are to be given.¹⁹ It may also be possible to give some of the treatment orally²⁰ or in lozenges.²¹

Penicillin had little or no effect on the strictly toxic or eruptive phase of the disease. In this respect it was similar to sulfonamides.²²

CONCLUSIONS

In patients with scarlet fever treated with penicillin intramuscularly, hemolytic streptococci disappear from the nasal and pharyngeal cultures within forty-eight hours, and if the treatment is continued for seven days the original types of streptococci do not reappear.

Penicillin solution given to similar patients by spraying the nose and throat four to six times a day has very little effect on the hemolytic streptococci in the pharynx but seems to keep the nose free from these organisms while the treatment is being continued.

In similar cases sulfadiazine given orally in full doses for seven days results in a suppression in the numbers of hemolytic streptococci in cultures obtained during the period of treatment only. In this respect the results were comparable to those obtained by others in cases of hemolytic streptococcal pharyngitis and tonsillitis.

The clinical and bacteriologic results suggest that early systemic treatment with penicillin in adequate doses continued for seven days may eliminate the hemolytic streptococcus carrier state and prevent complica-

tions due to this organism. The eruption and toxic manifestations of scarlet fever are not influenced by penicillin.

It should be emphasized that these conclusions are based on a very small number of cases and therefore are only tentative. They require corroboration and elaboration in a larger number of cases of various kinds of hemolytic streptococcal infections.

INTRAVENOUS ANESTHESIA FOR ORTHOPEDIC SURGERY

GEORGE J. THOMAS, M.D.

PITTSBURGH

In the past decade intravenous anesthesia has shown a definite and consistent increase in its application and use. I feel that this form of anesthesia has a definite place in orthopedic surgery for the following reasons:

1. The technic of administration is simple.
2. The induction period is short and pleasant.
3. The usual psychic shock is absent.
4. The depth of narcosis is controllable and sufficient for any orthopedic procedure.
5. It may be repeated without danger of becoming habit forming.

I am not attempting to advocate intravenous anesthesia for all types of orthopedic patients. I wish to emphasize that the contraindications for the use of the intravenous agents must be observed. Children under 7 or 8 years of age, unless very robust, are poor subjects. Apart from their natural fear and small veins, the inertia of the air and their narrow air passages hinder gaseous exchanges and create an undesirable situation in view of their relatively high oxygen requirements. Such patients do very well under tribromoethanol and ether anesthesia, since tribromoethanol prevents psychic shock, which children frequently show during the induction period.

Victims of accidents involving the extremities, who are in shock, do better with nerve block. If intravenous anesthesia is to be used, shock must be treated first, followed by anesthesia and surgery.

THE AGENT OF CHOICE

Among several intravenous anesthetics studied I found pentothal sodium to have the following advantages over other agents:

1. It is equally, if not more, powerful and rapid in action.
2. Twitching is rare.
3. Postanesthetic nausea and vomiting are less frequent.
4. Relaxation is more satisfactory.
5. Recovery is more rapid.

OPERATIONS ON PATIENTS IN PRONE POSITION

Intubation anesthesia is more suitable for patients who are in the prone position or any other position that hinders respiratory movements, or positions that are difficult in controlling the airway.

Preintubation Treatment.—Laryngeal irritability is increased under pentothal anesthesia. Coughing or vicious laryngospasm may occur during intubation. This, if persistent, will cause alarming cyanosis and cardiac embarrassment. This may be avoided by spraying the mouth and throat with 2 per cent pontocaine

or 4 per cent cocaine immediately on the patient's arrival in the operating room. The spraying is repeated before starting the intravenous administration of pentothal. The intubation is completed while the patient is in the usual position on the carriage. The patient is then transferred to the operating table in

Fig. 1.—Anesthetic technique for patient in prone position

a position suitable for surgery. The anesthesia is then continued with pentothal supplemented with equal parts of nitrous oxide and oxygen.

For operations below the twelfth dorsal vertebra I prefer to use a combination of spinal analgesia, pentothal, nitrous oxide and oxygen. The spinal tap provides analgesia to the area, the pentothal counteracts the toxic effect of procaine while the equal parts of nitrous oxide and oxygen provide a good tidal exchange. This technique is illustrated by figure 1. The patient is placed in a prone position on the operating table over the kidney elevator to facilitate the surgical procedure. The venipuncture for pentothal anesthesia is performed in the most accessible vein before the spinal tap is made. The subarachnoid tap can be made quite easily in this position without turning the patient on his side.

I have used spinal analgesia following the injection of lipiodol without any harmful reaction. I have not attempted spinal analgesia on patients who have had pantopaque.

TECHNIC FOR THE ADMINISTRATION OF PENTOTHAL SODIUM ANESTHESIA

Preoperative Medication.—Sufficient and proper preoperative medication is absolutely essential for a smooth pentothal anesthesia. Opiates are used, with special emphasis placed on the necessity for atropine. These preoperative agents control the parasympathetic hyperactivity and inhibit salivary and mucous secretions, thereby greatly reducing the incidence of complications such as coughing, sneezing and laryngospasm. The preoperative medication should be administered hypodermically thirty to forty-five minutes before the anesthetic.

Administration of Pentothal.—The dose cannot be accurately judged by the patient's weight, age, sex or metabolic state. The dose must be adjusted to each individual patient. In order to obtain the proper depth of narcosis for the particular type of operation, one must resort to the intermittent technique in the administration of this agent. In our institutions this technique is made possible with the use of an inexpensive apparatus. This consists of a small stand that can be clamped on an arm board. The base supports a reservoir for the pentothal solution, and an adjustable bracket attached to the stand holds a syringe. A two way stopcock is attached to the syringe, to each outlet of which is connected ordinary Dakin tubing 8 inches in length. One tube leads to the reservoir and the other to the arm. To the latter is attached a glass observation tube and a needle (fig. 2). Such equipment makes it possible to refill the syringe when necessary and to continue the intermittent technique indefinitely.

The operating field is prepared and draped. Venipuncture is performed after the skin has been surgically prepared. Three cc. of a 4 per cent solution of pentothal sodium is injected during a period of ten seconds. Because relaxation comes on more slowly than unconsciousness, it is very important that a pause of five seconds follow the injection of each 2 or 3 cc. of the agent. An additional 2 or 3 cc. is injected at the same rate as in the beginning, followed by another pause of five seconds. This procedure is continued until the desired relaxation is obtained. The air passage must be patent. Oxygen must be administered with a gas machine, with a nasal adapter or with a whistle-tip rubber catheter inserted to a distance of 5 inches through the nose and into the pharynx.

It must be remembered that, since the agent is given intermittently, the effect following the administration of each successive dose is increased. The pause between injections is highly important because the accumulated effect of the drug may come on very suddenly. Evidence of recovery is an indication that an additional 2 cc. or more of the solution is necessary. Caution regarding the speed of injection cannot be overempha-

Fig. 2.—Apparatus used in the intermittent technique of administering pentothal sodium.

sized. As in all types of anesthesia, the body has no active mechanism of defense against overdosage.

Intravenous anesthesia should never be started unless there is oxygen available, either alone or on a gas machine.

In surgery requiring more than thirty minutes I have successfully used the so-called "double setup"

(fig. 3). The supplemental solution, either glucose, isotonic solution of sodium chloride, plasma or blood, is given continuously, while the pentothal is administered intermittently when needed. This has been made possible by the use of a "manifold." The supplemental solution passes continuously through one limb of the

Fig. 3.—"Double setup" apparatus for administering the supplemental solution and pentothal.

manifold and the pentothal through the opposite limb. The male adapter of the manifold is attached to an intravenous needle. The supplemental solution flushes the needle, thereby preventing coagulation of the blood. The supplemental solution is desirable as a stimulant and as a restorative agent. This makes it possible to administer intravenous anesthesia in prolonged surgical procedures.

COMPLICATIONS AND THEIR MANAGEMENT

Complications with pentothal anesthesia are rare. However, some occur and should be handled without serious results. The most common is respiratory depression. The amplitude of the respiration rather than the rate is affected. It was found that oxygen administered through a mask or a catheter is frequently sufficient to stimulate the respiration. However, occasionally it is found necessary to administer nitrous oxide and nitrogen, in the meantime reducing the amount of pentothal. This technic has become quite popular with our staff.

Other complications which may occur either in deep or in light anesthesia are coughing, laryngospasm and hiccups. These may cause alarming cyanosis and perhaps cardiac embarrassment, if persistent. Such complications are undoubtedly due to parasympathetic hyperactivity. Should they occur under anesthesia, we aspirate the mucus or other material in the pharynx, deepen the anesthesia and immediately administer nitrous oxide and oxygen under pressure.

Trismus is another complication. This is undoubtedly a result of parasympathetic hyperactivity that can be controlled with atropine. Should this occur during anesthesia, a nasopharyngeal tube should be imme-

diately inserted and oxygen administered under pressure. Delay in this procedure may become serious.

Urticarial rash has appeared on three occasions in our series of cases. It occurred during the induction of the anesthetic and is an interpretation of idiosyncrasy of the patient to that drug. If pentobarbital sodium is given the night before operation, the patient will reveal this susceptibility and this type of anesthetic can be avoided. However, should the condition occur during anesthesia, the pentothal should be discontinued and 4 to 6 minims (0.25 to 0.37 cc.) of neosyneprine immediately administered intramuscularly. The anesthetic should then be continued with inhalation agents, preferably nitrous oxide or cyclopropane.

POSTANESTHETIC COMPLICATIONS AND THEIR MANAGEMENT

The most common postanesthetic complication is respiratory depression. For this reason all patients anesthetized with pentothal should have oxygen administered to them continuously after the operation until they have completely reacted. Furthermore, the entire nursing staff of all hospitals should be thoroughly trained in the proper management of patients receiving barbiturates. The nursing staff should be made to realize that the postoperative and postanesthetic care of patients is very important for uneventful recovery.

Postanesthetic opiates should be withheld, especially in the case of older patients, until the patient has completely reacted from the anesthetic.

If a patient has not reacted within two or three hours, it means that an overdosage of pentothal has been administered. In this case the patient should be treated in the following manner:

1. Keep the patient warm.
2. Administer oxygen continuously.
3. Aspirate the mucus from the throat frequently.
4. Give 3 cc. of metrazol intravenously. Repeat in five minutes if necessary. (Incidentally, I have found metrazol a very efficient denarcotizing agent as well as an excellent respiratory stimulant in sufficient dose.)
5. Give hypertonic sucrose intravenously for diuresis and dehydration of the brain and the lungs.
6. Give repeated small transfusions or plasma, which will be found to be helpful.

CONTRAINDICATIONS

Pentothal sodium should not be employed or recommended when there is a decided physiologic or mechanical interference with the respiratory function. Children under 7 or 8 years of age, unless very robust, are poor subjects. It is inadvisable to use this agent on patients suffering with respiratory embarrassment due to cardiac decompensation. I feel that pentothal is contraindicated in the presence of bronchiectasis, severe anemia and shock.

COMMENT

I have attempted to present a brief review on the technic of pentothal sodium for orthopedic surgery, with special attention to the complications and their management, and the contraindications. Pentothal is not a drug with which liberties may be taken. Special care should be exercised in maintaining an efficient airway at all times. A gas machine should always be on hand and ready for use should respiratory depression or other complications present themselves. Finally, the drug should be administered by a thoroughly trained anesthetist who is competent to deal with any situation that may occur during the administration of this popular but potent agent.

4006 Penn Avenue.

ABSTRACT OF DISCUSSION

DR. AUSTIN LAMONT, Baltimore: As Dr. Thomas has suggested, orthopedic procedures in general offer no contraindications to the use of pentothal sodium for anesthesia. There is, in fact, ample justification for the opinion that the condition of the patient is the most important factor to be considered in choosing an anesthetic agent and method, assuming that the choice is to be made by an anesthetist skilled in the use of all the common agents and methods. Some will doubtless differ with Dr. Thomas in regard to certain of his statements, e. g. that the administration of pentothal is advisable to counteract the toxic effect of procaine injected into the subarachnoid space, that a pause of five seconds is a sufficient interval between repeated injections of 2 or 3 cc. of pentothal, that the complications of coughing, laryngospasm and hiccups should be treated partly by deepening the level of anesthesia which may already be deep, that hypertonic sucrose should be administered intravenously to patients who have received an overdose of pentothal and so on. Dr. Thomas wisely reiterates the warning that one cannot take liberties with pentothal without endangering the patient and that the safe and proper administration of pentothal requires a thoroughly trained anesthetist and efficient apparatus. When after an ordinary orthopedic or other superficial operation a patient does not react within two or three hours or indeed within fifteen or twenty minutes, it will usually be found that the pentothal was administered by an anesthetist relatively inexperienced with the agent. Most anesthetists in civilian practice who have occasion to use much pentothal have found that patients will rapidly recover from the narcosis if careful attention is paid to maintaining a level of anesthesia no deeper than necessary with as little pentothal as possible, an accomplishment which is facilitated by the continuous administration of nitrous oxide and oxygen in a ratio of about 60 to 40. It is interesting to speculate on Dr. Thomas's explanation of the fact that he has found oxygen to be a respiratory stimulant. For although there are excellent reasons for maintaining in the alveoli a high tension of oxygen throughout pentothal anesthesia, it is probable that oxygen could appear to act as a respiratory stimulant only when the respiratory center is so depressed by lack of oxygen that its integrity is dangerously impaired, a condition which should be strenuously avoided during anesthesia with pentothal or any other agent.

DR. JOHN H. HUTTON, Portland, Ore.: I don't know of any specialty to which the remark "each man to his own poison" is more applicable than to the field of anesthesiology. Some returning service anesthesiologists are enthusiastic about the use of pentothal sodium for a variety of operations in which they probably would not have employed it in civilian practice. Apparently the results obtained in the treatment of many serious battle casualties have justified their change of views. Dr. Thomas speaks of the use of tribromoethanol for children. Administration of this drug in the ward in basal doses, 80 to 90 mg. per kilogram of body weight, does much to offset psychic shock. In my experience supplemental administration of analgesic or light anesthetic mixtures of nitrous oxide-oxygen have resulted in adequate and smooth anesthesia. The method is further justified if fireproof conditions must prevail. In regard to orthopedic operation performed with the patient in the prone position, such as laminectomy or spinal fusion below the twelfth dorsal vertebra, in our service spinal anesthesia unsupplemented has become the method of choice. A mixture of 11 mg. of pontocaine and 55 mg. of procaine diluted to a total of 3 cc. with spinal fluid at the time of injection between the second and third lumbar vertebrae has proved satisfactory for the average patient. The injection is made with the patient lying on his right side. After the injection he is turned on his back for two minutes and then placed in the prone position, the table being kept level at all times. Supplemental anesthesia has only rarely been required for operations lasting less than two hours. Likewise a dose of 8 mg. of pontocaine and 40 mg. of procaine in the same dilution and site of injection has proved most satisfactory for the average patient requiring pin fixation or osteotomy of the hip. Dr. Thomas mentions the

use of neosynephrine. It is an excellent drug for use during operations under spinal anesthesia. I have employed 3 minims intramuscularly for hypotension which is not due to shock and have been pleased with the quick elevating and sustaining effect on the blood pressure along with an improvement in tone and slowing of the pulse. One factor has been mentioned about pentothal sodium anesthesia that deserves even further emphasis. That is the importance of adequate nursing care in the immediate postoperative period. Fatal hypoxemias have resulted from inattention. Such instances can be attributed to the stress of too little help, but nevertheless it is inexcusable. Complicated apparatus for the administration of pentothal sodium may in some instances militate against the use of that drug. Such apparatus requires cleaning and is more or less troublesome. Its use may have a direct bearing on the economic relationship between the anesthesiologist and the hospital administration.

DR. C. C. YOUNT, Pittsburgh: It has been my privilege to be associated with Dr. George J. Thomas in many hundreds of orthopedic operations since he was made chief anesthetist at St. Francis Hospital. The most important improvement brought about is the change from inhalation anesthesia to intravenous anesthesia, more particularly in those cases in which the supine position and a long operative period are required—such as extensive spine fusion of the combined hip-Albee type as in scoliosis and tuberculosis and more recently in partial laminectomy for pathologic conditions in the intervertebral disk region. In the latter group a more recent plan of combined intravenous and spinal analgesia has been very helpful both to the operator and to the patient. Laryngospasm has been less frequent, and supportive treatment may be more easily administered by the anesthetic team. Anociassociation is more complete and the incidence of shock is lower. In my early surgical career I was on the staff in a hospital where spinal analgesia was being used extensively, and for a time I felt that spinal analgesia offered the best method in all operations below the umbilicus except in children. I now feel that there is a limited field for spinal analgesia exclusively, but a larger field for combined spinal analgesia with pentothal or other intravenous anesthetic agents. I have found the use of intravenous anesthesia especially useful in manipulations in adults requiring a rather short period of anesthesia and in children the inhalation of vinethene. Dr. Thomas has not mentioned local anesthesia, but I still prefer it in many minor operative procedures in orthopedic surgery, such as ingrown toenails, ganglion of tendons, biopsy of exposed bone tumors, some exostoses of bone, and in minor operations involving the digits. I have noted in recent years that the administration of anesthesia has become very diversified and considerable experience is necessary in selecting the proper anesthesia. I feel that this decision should be made after a brief review of each case with the anesthetist. If the surgeon has confidence in his chief anesthetist and his team, little concern and little attention to this feature of the operation need be given by the surgeon. The important position of the anesthetist on the operating room team should be more generally recognized both by medical personnel and by the public.

DR. MAYFR S. DEROY, Pittsburgh: Intravenous anesthesia is used in a high percentage of cases in our orthopedic service. Its use is limited, however, to the discretion of the department of anesthesia, the judgment of the members of which is final, and whose consultation is expected in all cases. Combination with spinal or inhalation anesthesia is also a problem for that department. Pentothal is advantageous in short procedures, such as back manipulations and fracture reduction. The fact that many patients will request intravenous anesthesia from previous experience or from conversation with other patients emphasizes the ease of induction from the patients' point of view. With elimination of the stage of excitement or struggle there is less chance of loss of position of fracture fragments. The longer procedures, such as laminectomy, spine fusion and hip reconstruction, do well with combined spinal and intravenous anesthesia. The patient is placed in the desired position and then anesthesia is begun. We have had no difficulty in giving spinal anesthesia with the patient in the prone position but prefer to give the intravenous first, followed by the

spinal tap. Thus a minimal amount of pentothal is used and the patient has no recollection of the procedure. In comparing intravenous and inhalation anesthesia, we are impressed by the relative safety of pentothal. We have had no deaths in several thousand cases. We have had no fear of explosion from gases in using the electrocoagulation apparatus or the electric saw. Proper preoperative medication will minimize complications such as spasm of the larynx. Relaxation is rapid and complete. The lessened nausea and vomiting in these cases is advantageous when a body cast has been applied. We are impressed by the ease of administration of fluids, using the double setup, and take advantage of administering saline solution, glucose, plasma or even blood. The essential fact remains that our satisfactory use of intravenous anesthesia has been in hospitals which have anesthetists well trained in its use. It should be used only by experienced persons and when so given is of great value.

SICKLE CELL ANEMIA, "A GREAT MASQUERADER"

EASILY RECOGNIZABLE WITH ROUTINE USE OF
DIAGNOSTIC PARAMETER

TRAVIS WINSOR, M.D.

AND

GEORGE E. BURCH, M.D.

NEW ORLEANS

Like syphilis, sickle cell anemia may present many clinical syndromes.¹ Some of these are easily recognizable, while others may imitate many disease states such as rheumatic fever, tuberculosis, Hodgkin's disease and acute surgical diseases of the abdomen, only to mention a few, to an extent that the differential diagnosis is learned only after proper hematologic study. Like syphilis, the disease may be so subtle as not to enter the mind of the clinician. Because of the fact that sickle cell anemia is such a great imitator and because it may remain so subtle, it is necessary, again as in syphilis, to study the blood routinely for sickle cell anemia in all Negro patients. In the past routine studies have not been done, as preparations of blood for sickling have offered certain difficulties.² A simple, rapid and accurate (the diagnostic parameter) method, described elsewhere,³ offers itself for the routine study of all Negro patients for the existence of active sickle cell anemia. For the past twenty-four months this test has been applied routinely to all Negro patients entering a medical service of the Charity Hospital. As in the case of routine serologic examinations for syphilis, this has resulted in the unexpected discovery of many patients with sickle cell anemia as a primary or complicating disease. For example, a routine search for sickle cell anemia by means of the diagnostic parameter in 612 consecutive Negro patients admitted to this one medical service resulted in the finding of 27 cases (4.4 per cent) of active sickle cell anemia. This culminated in an early and correct diagnosis, though often unexpected, in many patients who ordinarily may have not been found to have this disease. Needless to say, many of these would have been erroneously treated and subjected to surgical procedures, well known to be dangerous and usually contraindicated and unnecessary in active sickle cell anemia.

This report indicates the methods and results of the routine use of the diagnostic parameter in the management of Negro patients.

METHODS

Two methods may be employed in performing the test, one employing carbon dioxide (diagnostic parameter Δ_1) and the other venous stasis (diagnostic parameter Δ_2) to produce a retardation of the rate of erythrocyte sedimentation.⁴ These methods are again described briefly:

Tourniquet Technic (Δ_2).—A sphygmomanometer cuff is wrapped round the brachium and inflated to a pressure between systolic and diastolic and allowed to remain in place for approximately six minutes. Ten cc. of venous blood (the collection of dark blue blood indicates adequate stasis) is withdrawn and placed in a 10 cc. vial containing oxylate or citrate crystals as anticoagulant. A Wintrobe sedimentation rate tube⁵ is immediately filled, care being taken to prevent excessive loss of carbon dioxide, and the sedimentation rate determined. Approximately 3 cc. of the remaining blood is then transferred to a 50 cc. Ehrlenmeyer flask, which is rotated periodically at two minute intervals for fifteen minutes (adequate aeration or oxygenation is indicated by the bright red color) to facilitate the escape of carbon dioxide. A rate of sedimentation is then measured for the aerated sample. The diagnostic parameter Δ_2 is positive or indicative of sickle cell anemia when the difference between the sedimentation rates (uncorrected) of aerated and reduced blood

* Percentage increase in hematocrit of blood treated with carbon dioxide over blood treated by aeration.

H_{CO_2} = hematocrit of blood treated with carbon dioxide.

H_A = hematocrit of blood treated by aeration.

is greater than 20 mm. per hour. If the diagnostic parameter is between 0 and 20 mm. per hour the chances are more than 10,000 to 1 that the patient does not have sickle cell anemia. If greater than 20 mm. per hour the chances are 98 in 100 that the patient has sickle cell anemia.⁴

Carbon Dioxide Technic (Δ_1).—Between 5 and 10 cc. of venous blood is drawn without regard to the duration of the application of the tourniquet and placed in a vial containing an anticoagulant (oxylate or citrate

crystals). Two or three cc. is transferred to a 50 cc. rubber stoppered Ehrlemeyer flask into which fairly pure carbon dioxide is introduced or has previously been introduced. The flask is agitated at approximately two minute intervals for fifteen minutes or until the blood becomes dark blue. Two or 3 cc. of the original

and 65 mm. per hour); the average Δ_1 parameter for the 437 control patients was 5.5, the extremes being 0 to 24 mm. per hour, while the average for the 73 patients with sickle cell anemia was 53.5, the extremes being 29 to 77 mm. per hour. The definite grouping of individuals into those with large and those with small diagnostic parameters indicates the usefulness of the procedure as a diagnostic aid.

Chart 3 indicates the need for a high concentration of carbon dioxide in order to insure a satisfactory result for the parameter Δ_1 . At atmospheric pressure the percentage of carbon dioxide in the gaseous mixture employed to saturate the blood with carbon dioxide should exceed 95 per cent. In the performance of the parameter Δ_2 the use of a tourniquet for six minutes will give equally good results when carbon dioxide gas is not available. It can be seen from table 1 that the more severe the anemia the greater the tendency for the parameter to deviate from the normal. This was true whether or not the anemia was artificially produced by separating the erythrocytes and plasma and recombining them in various proportions, or the anemia of various degrees occurred naturally in patients. For example, in the instance of an artificially produced anemia the diagnostic parameter Δ_1 averaged 88.3 mm. per hour when the hematocrit averaged 6 per cent and 37 mm. per hour when the hematocrit averaged 40 per cent, remaining abnormally high in sickle cell anemia even in the presence of normal hematocrit readings.

Significant differences of diagnostic importance were also noted in the hematocrit determinations of the bloods treated with carbon dioxide and air in the patients with sickle cell anemia (table 2). In all of 10 patients with sickle cell anemia, adequate centrifugation of the sedimentation tubes after determining the

Chart 1.—Diagnostic parameters Δ_1 in 437 control individuals (normal subjects and patients with various diseases including anemias other than sickle cell anemia) and 73 patients with sickle cell anemia, showing the grouping about the parameter value of 20 mm. per hour.

sample (blood not treated with carbon dioxide) is placed in another open flask and aerated by intermittent agitation for about fifteen minutes or until the blood becomes bright red. Separate sedimentation rates are then set up using blood from each flask, the results being read in one hour. The parameter Δ_1 is positive or diagnostic of sickle cell anemia when the difference between the two rates is greater than 27 mm. per hour. The probable errors are as small as indicated for Δ_2 .

RESULTS

The results obtained with the diagnostic parameters Δ_1 and Δ_2 are summarized in charts 1 and 2. In the study of 175 control persons with various disease states, including many types of anemia, and 34 patients with sickle cell anemia, the diagnostic parameter Δ_2 did not give a false response in a single instance (chart 2). In 437 control patients and 73 with sickle cell anemia the diagnostic parameter Δ_1 also did not give a false response in a single instance. Sicklemia, that is, the condition of sickling without active sickle cell anemia, is not included in these studies. The average Δ_2 parameter for the 175 control subjects was 5.3, the extremes being 1 and 18 mm., while the average for the 34 patients with sickle cell anemia was 41.4 (extremes 29

Chart 2.—Diagnostic parameters Δ_2 in 175 control individuals (normal subjects and patients with disease states including various types of anemias other than sickle cell anemia) and 34 patients with sickle cell anemia, showing the clearcut grouping of patients above and below a diagnostic parameter value of 20 mm. per hour.

diagnostic parameters (Δ_1) revealed a definite increase in the hematocrit reading of the blood treated with carbon dioxide over that treated with air; increase in the hematocrit reading averaged 50.4 per cent (extremes 40 and 70 per cent) following treatment with carbon dioxide. The diagnostic parameter Δ_1 in these patients

averaged 50.7 mm. per hour (extremes 33 and 76 mm. per hour). Of a control group of 51 normal subjects and patients with other disease states, the average increase in hematocrit reading was only 10.9 per cent (extremes 4.3 and 21.4 per cent) following treatment with carbon dioxide. The diagnostic parameter in this

Chart 3.—Effect of the carbon dioxide concentration in air for fifteen minutes on the sedimentation rate of erythrocytes. The greatest effect is found in concentrations of 95 per cent or more.

group averaged 3.5 mm. per hour (extremes 0 and 19 mm. per hour). The difference was greater than 30 per cent in all of the bloods of the patients with sickle cell anemia, while none of the control subjects exceeded this value (chart 4). When an artificial anemia was produced (table 1) the mean increase in the hematocrit in patients with sickle cell anemia was 66 per cent (extremes 44.3 and 93 per cent) and in the control subjects the average increase was 19.2 per cent (extremes 11 and 22.8 per cent).

COMMENT

From the data presented it is obvious that the diagnostic parameters Δ_1 or Δ_2 are reliable tests for active sickle cell anemia. Since they are simple and require no special apparatus or materials, they can be used routinely. The results are obtained in not longer than an hour, usually in much less time, which increases their serviceability. This is particularly true when dealing with acute clinical problems which may be confused with sickle cell anemia. It has been the practice to check all results obtained with the diagnostic parameter by the less rapid sickling preparation. In no instance has the diagnostic parameter given false responses. Since sedimentation rates are so frequently employed with patients with acute or obscure clinical states, it is simple to modify this to include the diagnostic parameter when dealing with Negro patients. This entails little additional effort. Since the influences of carbon dioxide are so definite on the erythrocyte size as reflected in the hematocrit, the results of the diagnostic parameter can be checked by centrifuging the sedimentation tubes following the sedimentation determinations. The diagnostic value of the hematocrit is illustrated by chart 4.

Needless to say because of these accentuated changes in hematocrit readings occurring as the result of exposure of blood to carbon dioxide, grave errors in the determination of the mean corpuscular volume and in the mean corpuscular hemoglobin concentration may result in hematologic studies in sickle cell anemia. Errors in the determinations of the mean corpuscular hemoglobin do not occur, as the calculations do not involve the use of the hematocrit readings. Furthermore, because of the striking differences in the sedimentation rates and hematocrit readings following the application of a tourniquet, it is obvious that usual clinical correction charts for anemia⁶ apply only under special circumstances. The chart certainly does not apply for the

hematocrit readings and sedimentation rates of carbon dioxide treated blood. The process of collecting blood usually involves venous stasis with a certain amount of treatment with carbon dioxide from the tissues, so that the usual correction charts for anemia are unreliable in sickle cell anemia. These and other phenomena have been discussed in detail elsewhere.⁶

As stated previously, since the introduction of the diagnostic parameter as a routine clinical test on all Negro patients in a medical service at the Charity Hospital there resulted the unexpected discovery of 27 patients with active sickle cell anemia in 612 consecutive patients examined. Clinical value of this information is obvious. Needless to say many clinical difficulties, errors in diagnosis and unnecessary special laboratory procedures were avoided by the early and correct diagnostic evaluation of these patients. In many of the patients the disease was either subtle or strongly suggested clinical syndromes other than sickle cell anemia. The routine use of the diagnostic parameter in examining the Negro patients proved to simplify the clinical study in a manner similar to that in which routine serologic examinations for syphilis simplified the management of the nonsyphilitic and the syphilitic patients.

It might be well to add that during the course of the hematocrit and diagnostic parameter determinations the presence or absence of mild jaundice and often leukocytosis, both objective signs of diagnostic value in active sickle cell anemia, were revealed. In this series of 72 patients with active sickle cell anemia jaundice and leukocytosis were invariably present. McGavack⁷ found jaundice of the sclera in all but 10 of 214 patients with sickle cell anemia, indicating further the diagnostic importance of jaundice in active sickle cell anemia.

SUMMARY

Since sickle cell anemia is a great masquerader, a search for this disease should be made routinely in all Negro patients in a manner similar to that in which

Chart 4.—Scatter graph of the percentage increase in the hematocrit of blood treated with carbon dioxide over that treated with air in 51 control normal subjects and patients with other disease states and 10 patients with sickle cell anemia. A difference greater than 30 per cent may be indicative of sickle cell anemia.

routine serologic examinations for syphilis are made. Since the institution of the routine use of the diagnostic parameter in a medical service at Charity Hospital.

⁷ McGavack, T. H., and Nussbaum, C. C.: Skin Manifestations of Sickle Cell Anemia, *Urol. & Cutan. Rev.* 46:194-200 (March) 1942.

27 cases of active sickle cell anemia have been discovered among 612 consecutive Negro patients tested. This has resulted in an early, though often unexpected, correct diagnosis in many patients who may have been erroneously managed in a rapidly moving hospital medical service.

The change in hematocrit reading following the treatment of sickle cell anemic blood with carbon dioxide is of diagnostic value. In no instance did the diagnostic parameter give a false response. This is particularly important in view of the fact that it is a rapid procedure and therefore of great value in the management of acute medical and surgical problems among Negro patients.

THE MANAGEMENT OF CHRONIC MALARIA BETWEEN ATTACKS

WITH SPECIAL REFERENCE TO THE EFFECT OF
NICOTINIC ACID ON MALARIAL HEADACHE

LIEUTENANT COMMANDER MEYER A. ZELIGS
(MC), U.S.N.R.

Since its earliest description in ancient times, malaria has been the subject of repeated writings by a host of authors and scientific investigators. For the past sixty years, following the discovery of Laveran in 1884 of the malarial plasmodium in the blood of malarial patients, a tremendous impetus has been added to the interest and scientific investigation of this disease. Eleven years (1895) after Laveran's epochal demonstration Sir Ronald Ross discovered the mosquito vector in the transmission of malaria to human beings and thus established the second important milestone in our advance against this age-old scourge. These two outstanding contributions served to stimulate further study of this disease, and at the present time malaria is being widely investigated by many epidemiologists, military physicians and public health workers.

Because of the episodic nature of chronic malaria and the long asymptomatic intervals which characterize the course of the disease all previous studies, as far as could be ascertained by review of the literature, have been concerned entirely with the problems of prevention, diagnosis and treatment of the acute attacks per se, practically nothing having been written concerning the management of malarial patients between attacks. The reason for this is quite understandable. Prior to World War II there was little need to observe civilian patients with chronic malaria during the interval phases of their disease, as such persons were almost invariably able to carry on a normal ambulatory existence. However, with the outbreak of the war and its almost immediate spread to malaria infested areas, many thousands of military personnel were stricken and subsequently returned to the United States with this disease. We are now faced with an unprecedented situation as the result of this tremendous influx. The social and medical aspects of malaria are already the concern of many physicians, and knowledge of some of its common clinical features has become a matter of general clinical importance. It is my purpose in this paper, therefore, to acquaint physicians, both civilian and military, with some of the more common and occasionally distressing features occurring in the interval phase of this disease.

"POSTMALARIAL ASTHENIA"

It would be in order at this point to comment, for the purpose of better understanding and correct nosology, on the use of the term "postmalarial asthenia." Unfortunately this antiquated expression, once applied to victims of malaria in the tropics and characterized by cachexia, anemia and other ailments, is today still used by many medical officers and often serves as a cover-all for psychosomatic and other disturbances not necessarily of malarial origin. The debilitation which was so commonly observed among tropical natives and the malnutrition which was present concomitantly with malaria among the poor white inhabitants throughout the South who were afflicted with this disease traditionally accounts for the origin of the term "postmalarial asthenia." One must bear in mind that present day "war malaria" constitutes a different problem from that seen during peacetime. Almost all military personnel who have acquired malaria have done so as a result of having been exposed to this infection in a combat area. These men developed malaria while under unusual stress, and the element of fatigue, mental and physical, played an important role in rendering them susceptible to any infection. In many instances the initial malarial attack developed while the patient was in actual combat against the enemy, the chills and fever having been endured simultaneously with battle weariness, hunger, intense fear and exposure to wet and cold. Following removal from the field, with the usual supportive measures and the use of antimalarial drugs, recovery from the febrile attack usually occurred within a few days. After the acute episode, such patients were found to exhibit many symptoms, among which were included easy fatigability, irritability, weight loss, headache, backache and disturbed sleep. This syndrome was often diagnosed or interpreted as "postmalarial asthenia." Medical officers who have had occasion to care for malarial patients shortly after their removal from combat are well aware that generalized weakness constitutes a major complaint among such persons at that time. There is no doubt that malaria contributed to the development of this so-called state of "asthenia." Accurate appraisal of the total situation, however, will usually reveal that such symptoms of weakness or nervousness are attributable to the physical and psychologic stress of combat and are in many instances a form of combat or operational fatigue. This does not mean that frequent malarial relapses may not in themselves bring about weight loss, fatigability and other somatic disturbances which are included in the asthenic syndrome mentioned, but it is to be emphasized that, despite the vicissitudes of combat, these men, thanks to suppressive action of atabrine, though much fatigued, suffered relatively few or no malarial attacks during this period. It was after removal from combat and following the discontinuance of suppressive therapy that increase in such relapses occurred.

It is interesting to note that in a large group of malarial patients, after their return to the United States and following a period of at least three months of reconditioning, the incidence of "asthenia" was found to be negligible despite the fact that many of these men, no longer under any suppressive treatment, were known to have had malaria for as long as three years, and a good number of them had a history of as many as twenty-five to thirty acute attacks. One notes in such a group that when the symptoms of operational fatigue or other concurrent involvement, especially tropical infections such as amebiasis and hookworm,

are recognized and specifically treated, these patients recover most gratifyingly despite the systemic persistence of their malaria. It would appear, then, that "postmalarial asthenia" is a term which might well be abandoned, as it provides only semantic confusion and serves no useful nosologic function.

MALARIAL HEADACHE

There are, on the other hand, certain distressing symptoms which occur so often in persons with chronic malaria that one must indict the malarial parasite itself in some way as being specifically responsible for their occurrence. Most prevalent among these is headache. It is safe to state that between 15 and 20 per cent of military personnel with a history of chronic malaria are subject to periodic bouts of mild to severe headache. This headache is in itself one of the most disturbing features of the interval phase of this disease, and its alleviation has presented itself as a real challenge to those concerned with the "reconditioning" of malarial patients. Even among persons whose past history revealed complete freedom from any type of headache and who exhibited stable and well integrated personalities, the intractable headaches which they suffered since the onset of their malaria had in many cases caused secondary symptoms including mild depression, seclusiveness, irritability and other seemingly neurotic traits.

It might be well at this point to digress for a moment and briefly describe the special features of so-called malarial headaches and differentiate them from the other forms of headache which are encountered in any group of persons. The character of the headache, its location, periodicity, severity and other characteristic features, were carefully elicited in order to differentiate it from headache of nonmalarial origin. It was especially important not to include in this study persons who presented psychoneurotic features or other psychosomatic disturbances. The type of headache seen in patients with chronic malaria was usually bifrontal in distribution, almost always mild to moderate in severity, never intense or "bursting" in character and rarely described as being over the vertex or referred to as a "weight" or "pressure," as is frequently done by patients with headaches due to increased nervous tension. The typical malarial headache, if one may refer to it as such, is never hemispheric nor are there any neurologic prodromes, visual disturbances, nausea or vomiting, such as is seen in migrainous persons. The headache most often is present on arising in the morning and usually improves after the patient has been up for a few hours. A rather constant feature of patients with malarial headaches is the intolerance to any form of physical exertion, especially if it is performed in a hot sun. This almost invariably brings about a severe headache.

These persons were not benefited by the usual headache remedies. Salicylates, bromides, barbiturates and other analgesic or sedative drugs were, in our experience, found to be of no value in relieving this type of headache. Ergotamine tartrate administered hypodermically (0.5 cc.) to 15 selected patients, and amphetamine sulfate given orally (5 to 10 mg. doses) to 25 patients were found to be of no benefit and in several cases caused increase in the severity of the headache as the result of their vasoconstrictive action. It was soon realized that no drug or remedy was available which might effectively be used for the relief of malarial headache. Moreover, until better understanding of the altered physiology underlying such headache

was forthcoming, any therapeutic approach to this problem necessarily had to remain along empirical lines. This is true not only in regard to headaches of malarial origin but also of the whole problem of headaches in general, the physiologic mechanism for which is as yet but slightly understood despite the brilliant experimental researches of Wolff¹ and others on the mechanism of migraine and histamine headache.

It has been repeatedly observed that in cerebral malaria pronounced hyperemia of the brain is present and stasis of blood in cerebral capillaries occurs. Autopsy studies of patients dying of this form of malignant malaria reveal characteristic clogging of cerebral capillaries by parasite laden erythrocytes. The tendency for parasitized red blood cells to become "sticky" (isoagglutination) has been established by those who have studied this form of malaria.² Whether such a state of capillary stasis occurs in patients with benign tertian malaria has not been shown, but if such were the case, the headaches might plausibly be explained on the basis of capillary stasis causing slowing of the rate of cerebral blood flow with resultant venular congestion, focal cerebral edema and anoxia. With this rationalization as the possible mechanism of malarial headaches, it occurred to me that an innocuous drug such as nicotinic acid, known to produce vasodilatation and to enhance cerebral blood flow,³ might be clinically effective in relieving such a headache.

On the basis of this assumption, a group of patients whose only complaint was frequent and severe headache, attributed by the examiner to malaria, was selected for special study. Each of these patients was admitted and complete physical and neurologic examinations, including x-ray of the skull, were done. Careful manometric estimation of the cerebrospinal fluid pressure and complete laboratory studies of the spinal fluid were done in all the cases in this group. No significant changes were noted. To each of these patients an initial dose of 100 mg. of nicotinic acid was given orally. Within ten or fifteen minutes after ingestion of this medication the usual flush and cutaneous erythema was noted. The patient was observed for about an hour after taking the drug. Examination of thick blood smears, taken just before and thirty minutes after the administration of the nicotinic acid, failed to reveal the presence of parasites in the peripheral blood. Simultaneously with the development of the characteristic feeling of warmth or "glow" and shortly after the appearance of appreciable erythema of the face, chest and trunk which occurred in all the men who were given the drug, moderate to complete relief of the headache was noted in some persons about thirty to forty-five minutes after taking the drug. Duration of relief of headache varied with each individual but as a rule lasted for several days. In those cases in which the headache recurred every day and was present on arising in the morning, 50 to 100 mg. of nicotinic acid taken after breakfast usually gave relief for the entire day. In general, the drug was administered in accordance

with the individual needs as determined by the periodicity or frequency of the headache and was prescribed accordingly. Of 25 patients so treated, 10 stated that the headache had disappeared entirely, 8 noted moderate relief and 7 were not helped at all.

SUMMARY

1. A large number of military personnel with chronic malaria are now in evidencce. These men, though ambulatory and in most instances capable of normal activity, are still in need of continued observation and proper care.

2. The term "postmalarial asthenia" should be abandoned, as careful evaluation and clinical appraisal invariably betray the nonmalarial nature of this condition.

3. Malarial headache is the most common and most disturbing symptom during the interval between attacks.

4. Secondary neurotic-like phenomena such as mild mental depression, seclusiveness, lack of interest and intolerance to physical exertion often develop following prolonged persistence of malarial headache.

5. In a group of 25 selected patients with malarial headache, nicotinic acid given orally in 100 mg. doses was found to relieve the headache in 10 cases, caused moderate improvement in 7 and was of no benefit in 8.

6. In view of the pharmacologic safety of this drug and the absence of any other effective therapy, it is felt that it should be given a therapeutic try.

OXIDIZED CELLULOSE—ABSORB- ABLE GAUZE (CELLULOSIC ACID)

VIRGINIA KNEELAND FRANTZ, M.D.

AND

RAFFAELE LATTES, M.D.

NEW YORK

Dry gauze used to stanch bleeding in the open wound has, in the experience of most surgeons, been both life saving and hazardous. Hemorrhage has been checked which might otherwise have proved fatal, but the subsequent removal of the gauze which stuck to the raw surfaces often resulted in fresh bleeding, and the danger of infection was great. Packing frequently obscured infection in the depths of the wound and blocked drainage. In fact, so great is the risk of promoting infection by this means that strong directives against the use of tight packing in wounds have been issued by both American and British military surgeons.

Some time ago in the search for a nonirritating absorbable membrane for use in plastic repair of special structures such as tendons in a sheath, a material was proposed by Dr. Hans T. Clarke, professor of biochemistry at the College of Physicians and Surgeons, and was kindly released by Dr. W. O. Kenyon of the Eastman Kodak Research Laboratories for our study in advance of his publication.¹ This was oxidized cellulose,

From the Department of Surgery, Columbia University College of Physicians and Surgeons.

The gauze and cotton were supplied by Eastman Kodak Research Laboratories, Rochester, N. Y. (U. S. Pat. No. 2,332,990), through Parke, Davis & Company, Detroit.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and Columbia University.

1. Yackel, E. C., and Kenyon, W. O.: Oxidation of Cellulose by Nitrogen Dioxide, *J. Am. Chem. Soc.* 64:121-127 (Jan.) 1942. Unruh, C. C., and Kenyon, W. O.: Investigation of the Properties of Cellulose Oxidized by Nitrogen Dioxide, *ibid.* 64:127-131 (Jan.) 1942.

now known as cellulosic acid, and consisted of cellulose in the form of cotton, gauze and paper which had been subjected to oxidation by nitrogen dioxide. As a result of this, carboxyl groups—COOH—were formed which rendered the material soluble in dilute alkali. By altering the oxidation time the carboxyl content could be altered, and this percentage determined the chemical and physical properties of the material treated.

The preliminary experimental work to determine the reaction of animal tissues to the material was reported by Frantz.² The problem of sterilization had not at that time been solved. The product was used experimentally after boiling for three minutes in distilled water, as it does not withstand the autoclave.

Simultaneously Putnam³ reported the first clinical trials of oxidized cotton pledgets used, as unoxidized pledgets had previously been used in neurosurgery as patties soaked in thrombin solution. The oxidized cotton patties did not require removal.

All of this study to date had concerned the use of very small amounts of the material, and work is still in progress on the development of absorbable protective membranes. The handling of larger quantities of gauze, however, in freely bleeding lacerations of various tissues has been investigated. Originally we thought of it only as a packing to stanch bleeding which, happily, and contrary to the usage of ordinary gauze, could be left in closed cavities or, if desired, removed from open contaminated or infected wounds without sticking and causing fresh hemorrhage. This also implied that no blocking of drainage could take place with this material.

Accordingly studies were undertaken in animals, and to our surprise it became evident that the oxidized gauze was not just a packing like ordinary gauze but had a specific hemostatic action in its own right. This made the addition of a clotting agent, thrombin, superfluous even for cotton patties. Moreover, there was reason to believe that the acidity of the material might inactivate the enzyme to a certain extent. Needless to say, only oozing can be controlled by the simple application of the gauze. For brisker bleeding some pressure

Fig. 1.—At right, oxidized gauze in dilute laked blood; at left, control without gauze. The control was bright red. The gauze was brown and the supernatant fluid almost colorless. (*Ann. Surg.*, August 1944)

must be used, possibly reinforced with tamponade or with retaining sutures.

This specific hemostatic property seems to depend on the formation of coagula apparently consisting of salts of cellulosic acid and hemoglobin. It can be illustrated in vitro by immersing a strip of gauze in a

Fig 2—Section showing oxidized gauze in experimental wound of dog's kidney. In this and the following illustrations the wounds were made as nearly as possible comparable. This shows a section forty-eight hours after packing. The gauze is closely applied to the wound surface (Ann Surg, August 1944)

dilute solution of laked blood (fig. 1). If ordinary gauze is used there is no obvious change. Oxidized gauze so placed immediately begins to draw out all color from the solution and appears after some hours as a brown fibrillar mass in clear, colorless fluid.

In a bleeding wound the gauze swells, turns black and sticks (fig. 2). This adherence is about as strong as the true clot formed when fibrin foam⁴ or gelatin sponge⁵ is used as a carrier for thrombin for surface bleeding. In a deep laceration or cavity, as for instance a laceration of liver or kidney, or the prosthetic bed

Fig 3—Three weeks after packing. Remnants of gauze are seen in the marked box. The rest of the pale zone in the cortex is composed of large mononuclear phagocytes (see figure 6). There is fibrous reparative tissue at A.

after suprapubic prostatectomy, dry, oxidized gauze is easily handled and no delay is necessary to prepare fresh sterile thrombin solution. Moreover, in such lacer-

ations experimentally, the gauze used wet has been less effective than dry, even if the wetting has been in thrombin solution.

The experimental work (figs. 2-6) which led to clinical use of the material and the first clinical trials of gauze were reported by us in August 1944.⁶ The clinical use was made possible when the gauze was available sterile, in double glassine envelopes, prepared by Parke, Davis & Company. The material had been used in only 17 clinical cases at that time. In a more recent publication,⁷ 115 clinical trials were reported. Cases to date are shown in the accompanying table.

In the original tests for possible irritating qualities and for absorbability in various animal tissue, where implants were made in relatively avascular beds, such as peritoneum, joint cavities and subcutaneous tissue, there was frequently no blood combined with the gauze. Considerable variation in absorption time was noted, and it was not realized at first that this was in part a matter of blood in the sponge. A simple test using rats was devised for testing many absorbable materials.⁸ When the implants of sample lots of gauze were made without impregnation with blood, it was noted that these small implants, 1 cm square, eight ply, were sometimes entirely absorbed in the subcutaneous tissue

of the back as early as the fourth day. The animals as a rule were killed on the seventh day in order to allow for the development of any possible infection, but some were examined at an earlier time after operation. This rapidity of absorption of the material was not duplicated in the experiments in hemostasis, and accordingly, in 9 rats, implants were made after first soaking the gauze in blood obtained by aspiration of the heart. They were killed postoperatively at 1, 2, 4, 7, 11, 13, 20, 24 and 30 days respectively. There was progressive decrease in the size of the implant, but even at 24 days there was still a small residual brown mass. At 30 days it was not present. Microscopically these tiny residua show a broad zone of phagocytes and a few remnants of cellulose not invaded by fibrous tissue. Also there were no significant gross or microscopic evidences of inflammation at any time. The findings were comparable in this respect to those noted after implantation of the dry material.

Fig 4—Eight weeks after packing. There is no gauze present. The defect is chiefly filled with a minimum of fibrous tissue still containing renal tubules and glomeruli. The bulk of fibrous tissue present is at A, where it surrounds a pale zone of phagocytes. The cavity in the depths is one of the calices into which a small mass of granulation tissue projects and which contains some blood clot.

The only untoward effect, apparently, when the material is introduced into the tissues, is in bone. The acidity of the gauze is considered the probable cause of delay in the formation of the early callus in clean experimental fractures and defects. Ultimately, however, repair does take place, and there is, of course,

no significant delay when, in the open lacerated compound fracture, hemostasis is secured by this means and the gauze is removed in the course of one to three days. Some retardation of epithelization has also been observed, and oxidized gauze is not recommended for a surface dressing of open wounds, except for hemostasis, to be removed when it has served this purpose. In this connection it is well to place it so that it does not overlap the skin edges, where it will stick like dry glue in contrast to its jelly-like character against moist tissue. It is this property of becoming gelatinous in the tissue fluids which allows it to be removed from the open wound without starting fresh bleeding and which also is insurance against any possibility of blocking drainage.

Other clinical reports of the use of oxidized cellulose are those of Cronkite, Deaver and Lozner⁹ and Uihlein and his associates¹⁰ at the Mayo Clinic. In the majority of the cases in these two reports absorbable cotton was used not dry but as a carrier of thrombin. Further trial in general surgery and neurosurgery is reported by

Other absorbable materials are also in the stage of clinical investigation. These we have discussed in greater detail elsewhere.⁷ The most widely publicized is human fibrin foam, which must be used in conjunction with thrombin. The reader is referred to THE JOURNAL article¹² for references to the work initiated

Fig. 5.—Fifteen weeks after packing. The narrow V shaped shadow is fibrous tissue in which there are renal tubules and glomeruli but no gauze and no characteristic phagocytes.

in the Department of Physical Chemistry of the Harvard Medical School. Gelatin sponge ("Absorbable Sponge") is also used with thrombin. These two absorbable materials and absorbable gauze and cotton (cellulosic acid) have now been recommended by the Committee on Surgery of the Office of Scientific Research and Development for use by the Army and Navy. It is hoped that clinical trial of all three materials will be undertaken by many investigators to determine as soon as possible the fields of usefulness.

Fig. 6.—Appearance under higher power four and a half weeks after packing, showing a broad zone of typical phagocytes immediately adjacent to kidney parenchyma. No gauze is seen. (Ann. Surg., August 1944.)

COMMENT

A brief review of the experimental and clinical investigation of absorbable gauze and absorbable cotton has been presented. The materials have been found to be

Clinical Notes, Suggestions and New Instruments

CORD TRANSFUSION IN THE MANAGEMENT OF A PREMATURELY DELIVERED INFANT WITH ERYTHROBLASTOSIS FETALIS

CLIFFORD H. HARVILLE, M.D., WARSAW, N. Y.

The basic role of the Rh factor in the pathogenesis of erythroblastosis fetalis is now well established. Concerning the prevention and treatment of this condition, however, such unanimity of opinion is lacking. All authorities agree that, for an infant born alive with manifestations of erythroblastosis, the treatment is prompt transfusion with compatible Rh negative blood. If irreversible changes are not already present, this is life saving, and such reduction in mortality as has to the present been effected is attributable largely to this therapy.

With the hope of further reducing the high toll still exacted by this disease, premature termination of pregnancy has been advocated in order to limit the period of intrauterine hemolysis. The principal division of opinion that exists in relation to the therapy of erythroblastosis is concerned with the advisability of this procedure. Potter,¹ Javert² and other investigators who have contributed extensively to the literature of the subject have expressed the opinion that early delivery in these cases is rarely justified except for maternal indication. The position is taken that pregnancy cannot be terminated sufficiently early for the fetus to escape hemolytic disease and that the added handicap of prematurity more than offsets any advantage to be gained by shortening the period of intrauterine hemolysis. Proponents of early delivery believe, however, that a few weeks of prematurity entail much less hazard for the fetus than an equal period of continuing exposure to the isoantibodies accumulating from the mother's blood. It is felt too that this is the only therapy at present available which gives promise of salvaging a further percentage of these infants.

Final evaluation of this therapeutic procedure, which must await reports of a larger experience in its use, will no doubt be largely conditioned by our success in dealing with the hazard of prematurity, admittedly somewhat increased in the presence of hemolytic disease of the fetus. Careful attention to the principles of premature care in the management of these infants is manifestly essential. Too great a degree of prematurity is certainly not desirable, and pregnancy should probably be continued to approximately four weeks of term. Experience indicates that this is sufficiently early to insure the recovery of a considerable number of children who would not survive if pregnancy should be continued to full term. These infants, needless to say, should be delivered only into the most favorable environment. The more drastic methods of inducing labor are probably best avoided, and if simple medical induction fails it is felt that cesarean section merits consideration. Analgesia and general anesthesia are interdicted.

A neglected procedure which I believe to be of the greatest value in the management of these prematurely delivered infants

is the use of the umbilical vein for the initial blood transfusion. This is a technically simple procedure which involves minimum handling of the infant and obviates the traumatization incident to venipuncture, factors of vital importance in this critical initial period of premature management. The faulty oxygenation and tendency to cyanosis characteristic of the premature infant is accentuated in the presence of hemolytic disease. Anoxemia results not only from the reduction in the number of red blood cells but also from the preponderance of macrocytes. These cells are less efficient carriers of oxygen than are normocytes, a characteristic also of erythroblasts. The immediate need in these infants is to combat this critical anemic anoxia. This is accomplished most promptly by the immediate transfusion of blood through the umbilical vein. Prothrombin, frequently deficient in erythroblastotic infants, is probably more promptly supplied in this way than by the vitamin K preparations also given routinely to these infants as well as to the mothers prior to delivery.

The simplicity of this method and the promptness of blood administration it assures commend it also for the initial transfusion of the full term infant suspected of having erythroblastosis. It might well prove life saving in the occasional infant such as the one mentioned by Wiener,³ who he states would have died had blood not been given within fifteen minutes of its birth.

A survey of the literature on erythroblastosis, which includes a number of papers detailing transfusion methods, has yielded no mention of the umbilical vein having been used for giving blood to infants with this disease. Its use, however, was found to have been suggested by Mayes⁴ in a paper dealing with routine cord transfusion in premature and immature infants, in which he states that, "if hemorrhagic disease or erythroblastosis is suspected, cord transfusions may be of benefit."

The following case report illustrates the successful use of cord transfusion in conjunction with early delivery in the management of erythroblastosis fetalis.

REPORT OF CASE

Mrs. G. M., white, aged 30, quintipara, sextigravida, consulted me on Nov. 17, 1944. From the menstrual history, corroborated by uterine mensuration, it was estimated she would be at term April 5, 1945. She gave the following obstetric history: Her first three pregnancies resulted in the delivery of normal children who are all living and well. The fourth child became deeply jaundiced shortly after birth, the jaundice persisting for about ten days. This child survived and is also well. Her fifth pregnancy resulted in the delivery, March 24, 1945, of a full-term jaundiced infant who died on the fourth day. The findings at necropsy were those of severe hemolytic disease of the newborn with pronounced selective jaundice of the basal ganglia of the brain (kernicterus).

Blood studies showed this woman to be type AB Rh negative. Serologic tests for syphilis were negative. The husband was type O Rh positive and each of the four surviving children was found to be Rh positive, indicating the father to be homozygous with respect to the Rh factor. On Feb. 7, 1945 anti-Rh agglutinins were demonstrated in the patient's blood in low titer. With this obstetric history and the virtual certainty that the fetus in this pregnancy was Rh positive, premature delivery seemed to us to offer this infant the best, probably the only, chance for survival.

On March 6, 1945, thirty days before estimated term, with the infant in apparently good condition, medical induction of labor was attempted, without resort to rupture of the membranes or other surgical methods. This failing, on March 8 a cesarean section was performed under local procaine anesthesia by Dr. Henry S. Martin. The umbilical cord was clamped immediately after delivery to exclude the blood from the placental circulation, and 60 cc. of blood from a type O Rh negative donor were given the infant through the umbilical vein.

From the Obstetrical Service, Wyoming County Community Hospital.

3. Wiener, A. S.: The Rh Factor in Therapy (symposium), *New York State J. Med.* 45: 302 (Feb. 1) 1945.

4. Mayes, H. W.: Cord Transfusions in Newborn Infants, *Am. J. Obst. & Gynec.* 48: 36 (July) 1944.

Studies of blood aspirated from the cord vein revealed a hemoglobin content of 8 Gm. per hundred cubic centimeters and a red blood cell count of 2,690,000, with a preponderance of macrocytes and pronounced polychromatophilia. There were but 7 erythroblasts reported per hundred leukocytes. The icterus index was 100. The infant's blood type was subsequently found to be O Rh positive.

The baby, a girl, breathed spontaneously. Its general condition, except for a rather pronounced pallor, seemed good. Clinical icterus was doubtfully present at birth but was definite when checked three hours later. The jaundice gradually deepened, reaching its maximum intensity about thirty hours after birth and then was essentially unchanged through the fifth day of life, after which it gradually lessened.

On the second day (March 9) examination of the peripheral blood showed a hemoglobin of 9.6 Gm. and 6 erythroblasts per hundred white blood cells. Failure of these cells to increase after birth as they have been observed to do in untreated cases when initially low in number was quite possibly attributable to the initial blood transfusion. A second transfusion of 90 cc. of whole blood from an O Rh negative donor was given at this time through an incision in the greater saphenous vein, the scalp veins being of unusually small caliber. Following this the red cell count was 5,700,000 and the hemoglobin content 17.24 Gm., these levels being maintained through the second week of life. During the third week there was a gradual lowering of these values, so that prior to the infant's discharge from the hospital on March 28 the red cell count was 3,110,000 and the hemoglobin 10 Gm. On April 2 the baby was seen for a checkup, and although her excellent weight gain had been continued and her general condition was good, she had again developed a definite pallor. A blood check showed an erythrocyte count of 2,900,000 and a hemoglobin of 8.2 Gm. There were no pathologic cells. She was given 100 cc. of whole O Rh negative blood with a return to normal red cell and hemoglobin values, and with the administration of iron these have continued at optimal levels to the present. Now at 4½ months the baby's development has been in all respects normal, and her weight is that of an infant of the same age born at term.

Anti-Rh agglutinins were not demonstrated in the mother's blood ten days after delivery with the usual technic. Facilities for testing for the presence of inhibitor or blocking antibodies were not then available.

COMMENT

The evidence in this case seemed to justify the belief that this infant would have little chance of survival if pregnancy was continued to full term. The fatal erythroblastosis with kernicterus manifested by the previous infant indicated that there was already in that pregnancy an extreme degree of sensitization of this mother. Experience has established that the intensity of maternal immunization increases in each succeeding pregnancy in which the fetus is Rh positive, resulting inevitably in progressively more severe manifestations of erythroblastosis in successive infants. The evidence that the father was homozygous with respect to the Rh factor, indicated that the infant possessed this factor.

The extent of the hemolysis present in this fetus four weeks before term, as evidenced by the degree of anemia and the high icterus index, would appear to confirm the belief that this infant would almost certainly not have survived had pregnancy been continued to full term.

SUMMARY

The case reported lends support to the thesis that in carefully selected cases of erythroblastosis fetal delivery is a rational therapeutic procedure.

Cord transfusion, hitherto neglected in these cases, is an important adjuvant procedure in the management of the prematurely delivered erythroblastotic infant. It is the method of choice for the initial transfusion also of the full-term infant suspected of having this disease.

88 North Main Street.

FAILURE OF CHOLINE CHLORIDE TO AUGMENT ANEMIA IN CIRRHOSIS OF THE LIVER

JANET WATSON, M.D., AND W. B. CASTLE, M.D., BOSTON

The report by Davis¹ of the production of hyperchromic anemia in dogs by the administration of choline chloride is of considerable interest in view of the increasing use of this substance in the treatment of liver disease in man.² Cartwright and Wintrobe³ recently gave choline chloride to 3 men over a period of ninety days without any hematologic effect. However, since none of their patients was suffering from hepatic disease, it seems worth while to report briefly a hematologic study of the effect of choline in a patient with cirrhosis of the liver and macrocytic anemia.

Davis¹ produced anemia in dogs by giving choline chloride orally in a dose of 10 mg. per kilogram of body weight daily for at least twenty-five days. When a definite anemia was established, the dosage was successively increased to 20 and 30 mg. per kilogram. There was said to be a reduction of 30 to 43 per cent in the red blood cell count, within seventy to ninety days. Our patient, T. T., aged 60, had had an extensive

* Daily intravenous administration of 1.0 Gm. of choline chloride begun.

† Daily oral administration of 1.0 Gm. of choline chloride begun.

intake of alcohol for many years and showed evidence of pronounced hepatic insufficiency in all the liver function tests. He was given choline chloride⁴ in a 5 per cent aqueous solution in a dose of 17 mg. per kilogram of body weight daily for seventy days, by intravenous administration for the first thirty days and by oral administration for the remaining forty days. This represented a total daily dose of 1 Gm. During the period of choline therapy the patient was maintained on the regular hospital diet and received no other medication. The hematologic data are shown in the accompanying table. It will be seen that on admission the patient had a macrocytic anemia. This was slowly improving before choline therapy was begun and continued to improve during therapy.

Dr. Watson is Commonwealth Fund Fellow.

Miss Ruth Pearson performed the blood examinations. From the Thorndike Memorial Laboratory, Second and Fourth Medical Services (Harvard), Boston City Hospital, and the Department of Medicine, Harvard Medical School.

2. Brown, G. O., and Muehler, R. O.: Treatment of Hepatic Cirrhosis with Choline Chloride and Diet Low in Fat and Cholesterol, *J. A. M. A.* 119: 1403 (April 18) 1942. Russakoff, A. H., and Blumberg, H.: Choline as Adjuvant to Dietary Therapy of Cirrhosis of Liver, *Ann. Int. Med.* 21: 648 (Nov.) 1944.

3. Cartwright, G. E., and Wintrobe, M. M.: Effect of the Administration of Choline Chloride on the Hematologic Picture in Human Beings, *J. A. M. A.* 127: 911 (April 7) 1945.

4. Supplied by Dr. George Hazel, Abbott Laboratories, North Chicago, Ill.

CONCLUSION

Choline chloride, in a dose of 17 mg. per kilogram of body weight given daily for seventy days to a patient with cirrhosis of the liver and macrocytic anemia, did not intensify the anemia. In fact, during this period the red blood cell and hemoglobin values progressively increased.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, Secretary.

SPERTI IRRADIATION LAMP MODEL HI-41 ACCEPTABLE

Manufacturer: Sperti Corporation, Norwood Station, Cincinnati 12, Ohio.

The Sperti Irradiation Lamp Model HI-41 is a combination ultraviolet and infra-red generator. Its radiation characteristics are such that it qualifies as a sun lamp. The firm claims that it produces an erythema in 3 minutes at a distance of 18 inches. The lamp will do therapeutically anything that can be expected from an acceptable sun lamp.

The Sperti Irradiation Lamp was investigated in a laboratory acceptable to the Council. The lamp was operated according to the manufacturer's instructions enclosed in the package. It was connected to a regulated 120 volt alternating current supply to insure constant operating conditions. An alternating current ammeter was placed in the supply line, and a voltmeter across the lamp terminals. When tested, the current supplied to the lamp was 3.7 amperes at 113 volts.

The Council investigator reported:

1. Spectral Radiative Measurements.

The relative intensities measured with a quartz-fluorite achromatic spectroradiometer, corrected for absorption by the lenses, etc., are given in the accompanying table.

Wavelengths— Angstroms	Relative Intensity
3132	113.0
3024	32.0
2967	11.8
2894	2.0
2804	2.3
2654	0.5
2537	0.0
Total	160.8

The amount of radiation of wavelengths 2,800 angstroms and shorter is only about 0.3 per cent of the total.

2. The total ultraviolet radiation of wavelengths 3132 angstroms and shorter measured along the central axis, at a distance of 2 feet (61 centimeters) from the edge of the reflector (64 centimeters from the front edge of the burner), when operated on 115 volts (alternating current) was 133 microwatts per square centimeter, which is 35 to 40 per cent above the minimum requirement. This ultraviolet generator, therefore, complies with the Council's requirements in spectral and total output of ultraviolet for acceptability as a sun lamp.

3. The total radiation of all wavelengths, measured along the central axis, at a distance of 2 feet from the reflector, was 12,700 microwatts per square centimeter. Of this amount, only 6.7 per cent was transmitted by a cell of water 1 centimeter in thickness, showing that most of the infra-red radiation is of wave lengths longer than 1.2 microns, which is not deeply penetrating. While the total output of infra-red is appreciable, it is only about $\frac{1}{3}$ to $\frac{1}{4}$ that of an infra-red generator designed for that purpose.

The Sperti Irradiation Lamp operates on either alternating or direct current. Its height, extended, is 5 feet 6 inches and collapsed is 3 feet 11 inches. Its weight packed is 29 pounds and unpacked, 23 pounds. The finish is chrome and hard-baked cream enamel. The stated operating wattage is given as 475. The Council test shows 734 watts.

The Council on Physical Medicine voted to accept the Sperti Irradiation Lamp, Model HI-41 for inclusion in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The following statement has been authorized for publication by the Council. AUSTIN SMITH, M.D., Secretary.

DRUGS SOLD IN FOREIGN COUNTRIES

From time to time the Council office has been requested to supply information on drugs which are made available in other countries. Many of these inquiries arise because of treatment undergone by patients from other countries, because of drugs used by physicians who have resided in other countries but who are now in the United States and because of publicity given by the press to drugs developed or sponsored elsewhere. Drug and pharmaceutical manufacturers and distributors in the United States are invited to supply information concerning the names, actions and uses, American equivalents and other useful data so that the files of the Council office may be as complete as possible and so the best information service can be provided to its inquirers. At the same time readers of this column are invited to make use of the information in the Council files by directing inquiries to the Secretary of the Council, in care of the American Medical Association, 535 North Dearborn Street, Chicago 10.

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

VITAMIN B COMPLEX SYRUP.—A syrup prepared from a concentrated extract of dried brewers' yeast and an extract of corn processed with *Clostridium acetobutylicum*, with inverted cane sugar 40 per cent w/v and natural flavoring.

Actions and Uses.—Proposed for prophyllaxis and treatment of conditions arising from deficiency of the vitamin B complex. VI-CO PRODUCTS CO., CHICAGO

Vitamin B Complex Syrup: Each 5 cc. contains thiamine hydrochloride 1.5 mg., riboflavin 1.0 mg., pyridoxine hydrochloride 0.5 mg. and nicotinic acid 7.0 mg., with other vitamin B complex factors as extracted from 10 Gm. of dried brewers' yeast.

U. S. Patent 2,193,876 (March 19, 1940; expires 1957).

THEOPHYLLINE ETHYLENEDIAMINE (See New and Nonofficial Remedies, 1944, p. 373).

The following dosage forms have been accepted:

BAILOW-MANEY LABORATORIES, INC., CEDAR RAPIDS, IOWA

Tablets Aminophylline: 0.1 Gm. and 0.2 Gm.

AMERICAN PHARMACEUTICAL CO., INC., NEW YORK

Tablets Aminophylline: 0.2 Gm. enteric coated with shellac.

CALCIUM LEVULINATE (See New and Nonofficial Remedies, 1944, p. 457).

The following dosage forms have been accepted:

CHEMO PURO MANUFACTURING CORP., LONG ISLAND CITY, N. Y.

Calcium Levulinate: 30 Gm. and 480 Gm. bottles.

CARROLL DUNHAM SMITH PHARMACAL CO., ORANGE, N. J.

Calcium Levulinate Injection 10% W/V: 1 Gm. in 10 cc.

BISMUTH SUBSALICYLATE (See New and Nonofficial Remedies, 1944, p. 236).

The following dosage form has been accepted:

THE SMITH-DORSEY CO., LINCOLN, NEB.

Bismuth Subsalicylate in Oil with Chlorobutanol: 50 cc. vials. A suspension of bismuth subsalicylate in peanut oil containing in each cubic centimeter bismuth subsalicylate 0.13 Gm. with 3 per cent chlorobutanol added.

SATURDAY, NOVEMBER 17, 1945

THE HILL-BURTON HOSPITAL CONSTRUCTION BILL

The Senate Committee on Education and Labor, after what has obviously been extended and thoughtful consideration, has reported with approval a revised measure (S. 191) for federal aid in the construction of hospitals and related facilities. Several important amendments are suggested by the committee.

The reported bill provides for a five year program and authorizes annual appropriations of \$75,000,000 for each of the five fiscal years, plus unappropriated and unexpended balances, as compared with \$100,000,000 in the original bill for the first year and an unlimited authorization thereafter. In the original bill an appropriation of \$5,000,000 was authorized for state administrative expenses. The committee has eliminated this authorization, taking the position that the states should be able to handle this feature without federal aid. Federal funds to be made available by this legislation will be allotted according to a new formula devised by the committee which eliminates administrative discretion in its application.

Misgivings had been felt by many because the term "public health center" was defined in the bill as a publicly owned facility for the provision of public health services and medical care. The reported bill eliminates the italicized words, thus limiting the functions of such centers to the provision of public health services, the scope of which will be determined by state law.

As introduced, the bill required a state plan to embody a hospital construction program which would be in accord with "standards" prescribed by the Surgeon General with the approval of the Federal Advisory Council. The Senate committee concluded that the independence of the states in carrying out their plans will be better preserved if the Congress specifies general requirements and limits the federal government's regulatory control to those requirements. These general requirements are set forth specifically in the amended bill. They relate in the main to the number and general

manner of distribution of hospitals to be constructed under the program. The scope of the federal regulatory powers as contemplated by the requirements is entirely consistent, in the opinion of the committee, with effective federal control of appropriated moneys.

The designation of the council to collaborate with the Surgeon General, on the federal level, in carrying out the purpose of the bill has been changed from the Federal Advisory Council to the Federal Hospital Council for the reason that its functions, the committee points out, are not merely advisory. Provision is made for the appointment by the council of special advisory and technical committees. The membership of the council has been modified to include three members to represent consumers of hospital services, who must be persons familiar with the need of hospital services in urban or rural areas.

During the course of the hearings on the bill, representatives of the Association suggested the advisability of including a provision, similar to the one contained in the Lanham act, to make it clear that federal control could not be exercised over the operation and maintenance of hospitals constructed under the program. Such a proscription is contained in the reported bill. To prevent the transfer of a hospital constructed under the program to a transferee not approved by the state agency, a provision has been added authorizing the United States to recover the federal percentage of the value of the hospital at the time of the transfer. A similar authority may be exercised if a nonprofit hospital ceases to remain in that category.

A reservation to the favorable report of the committee was filed by its chairman, Senator James E. Murray of Montana, a co-sponsor of the Wagner-Murray-Dingell bill. Senator Murray expressed the belief that the hospital bill includes a "bad and dangerous administrative arrangement" in that it assigns certain essential administrative functions to the Federal Hospital Council; that the bill devolves too much authority on the states with respect to the use of federal funds, "a dangerous and unwise proposal," and that federal regulatory powers should be extended over the operation and maintenance of hospitals. He emphasizes a conviction that S. 191 has only limited value and urges the enactment of legislation to solve the problem of paying for hospital and medical costs along the lines which Senator Wagner and he have worked out in S. 1050, "by broadening and strengthening the social security program."

The reported bill presents ample evidence of the desire of the Senate committee to offer a constructive program to be administered under proper safeguards. In the words of the committee report, "seldom has a subject received more careful consideration by any committee of the Congress than has the pending measure."

DO PIGEONS SPREAD VIRUS PNEUMONIA?

Extensive surveys of pigeon lofts and sampling of the pigeon populations throughout the country have shown that from 20 to 40 per cent of pigeons have in their serums antibodies which indicate that they have been at some time infected with the virus of ornithosis. Necropsies made on the bodies of pigeons and inoculation tests on mice with emulsions of the tissues of the spleen and of the kidney have shown that a variable percentage of pigeons may actually have living virus in the body. However, only a relatively small percentage of all pigeons are "open" carriers—that is to say, give off the virus in such form that they might infect other pigeons or human beings. Studies made by the George Williams Hooper Foundation of the University of California show that discharge of virus from the bowel of the pigeon is quite irregular and that many pigeons are "closed" carriers and noninfectious although serum positive.

When pigeons are crowded in lofts or cages, the latent infections may temporarily relapse into clinical infections and there may be massive shedding of the virus. The droppings in such cages remain infectious. When the material becomes dry, it is readily dispersed into the air by the fluttering birds. Therefore lofts in backyards or receiving pens for racing pigeons are much more likely to be foci for dissemination of infectious material than are the wild pigeons in city parks and around public buildings.

Danger to the human being comes from intimate contact with pigeons such as occurs when cleaning dirty lofts or when standing close to cages in which racing pigeons are received. Evidence indicates also that the picking up of sick pigeons in the park, bringing the birds home or killing and cleaning pigeons for food has likewise been followed by human infection with ornithosis. Apparently, then, it is possible for a human being to become infected from inhaling virus in dusts of streets or parks where flocks of pigeons congregate and their droppings soil the surroundings. However, actual studies seem to show only an exceedingly few cases that may have developed in this manner.

At present authorities in epidemiology are convinced that the risk is not significant and that the sensational, irresponsible, speculative publicity that has recently appeared in newspapers in some of our large cities is not warranted by any scientifically established evidence. Moreover, studies have been made which indicate that other species of birds are likewise carriers and shedders of viruses like those of psittacosis. Apparently these birds have not come under the suspicion of public health authorities.

In recent years great numbers of cases of atypical pneumonia due to virus have been reported all over the United States. Many of these cases have occurred in areas like camps and barracks where contact with

pigeons is minimal, if it occurred at all. Despite the demonstration that some cases of human virus pneumonia have seemed to follow association with pigeons, the authorities do not believe that this represents the main method of spread of the disease. Apparently direct contact between human beings is the method by which most of the cases occur.

The proposal has been made that all the wild pigeons of large cities be eliminated. Until the statistics in any city present conclusive evidence that human infections due to exposure to pigeons in the streets and parks are fairly common, such action is not warranted. What assurance can there be that pigeons will not reinvade cities after the original pigeons are removed? Obviously backyard pigeon lofts and pens containing racing pigeons and homing pigeons are not affected by indiscriminate destruction of wild pigeons. Furthermore, removal of the pigeons will not in any way minimize the possibility that parrakeets, love birds, canaries and other birds and fowl act as reservoirs for viruses.

MENKIN'S ANTINECROSIN (ECLAMPSIA ANTITOXIN)

In 1940 Smith¹ of the Fearing Research Laboratory, Brookline, Mass., demonstrated that the normal human menstrual discharge is highly toxic for rats and rabbits. Subsequent studies² have shown that its toxicity varies in direct proportion to the amount of endometrial debris. From this Smith concludes that the toxin is probably a specific autolytic product of the endometrial cells. The toxin is apparently a euglobulin. This euglobulin is highly antigenic for rabbits, giving rise to an antitoxic serum that will protect rats from multi-lethal doses of menstrual discharge.

While this work was in progress, Menkin³ of Harvard Medical School reported the presence of a similar toxic euglobulin in canine inflammatory exudate. For this toxin he proposed the name "necrosin." He found subsequently that necrosin could be fractionated by differential solubility methods. One of the fractions is a nontoxic pyrogenic factor, for which he proposed the name "pyrexin." He found that pyrexin is absent from normal blood serum but is present in appreciable amounts in the serums and urines of animals with a concomitant inflammation.

Parallel tests⁴ between human menstrual toxin and canine necrosin have shown that within the limits of the experimental error the two substances are qualitatively and quantitatively identical. On subcutaneous injection both will produce death within forty-eight

hours in 19-21 day old rats. The pathologic findings in rats receiving lethal doses of the two euglobulins are identical. Given intravenously to rabbits both are pyrogenic, small amounts causing a 2.5 to 5 degree F. rise in rectal temperature by the end of three hours. Both will liquefy the human fibrin clot. Both are antigenic for rabbits, inducing the production of antitoxins and precipitins and giving 100 per cent identical cross reactions. Smith considers this conclusive evidence of the complete identity of his human menstrual toxin and Menkin's canine necrosin.

Assuming this identity, Menkin's necrosin antiserum (precipitin) could be used for the detection of menstrual toxin in human tissues and body fluids. Such an anticanine serum presumably would not give interfering cross reactions with normal human tissue products. Using this antiserum, Smith⁵ found that factors identical with menstrual toxin not only are present in the circulating blood of menstruating women but also are present in even higher titer in the bloods of preeclampsia and eclampsia patients. The substance, however, is absent from the serums of normal nonmenstruating and normally pregnant women.

Since Menkin's necrosin antitoxin will prolong the survival time of rats after multilethal doses of menstrual toxin, its possible therapeutic value in human eclampsia is now under investigation. A similar protective substance has been found in the pseudoglobulin fraction of human menstrual discharge and in the venous serums of menstruating and eclampsia patients. This human antitoxic pseudoglobulin is being further investigated as a possible therapeutic agent.

Current Comment

WAR MEDICINE BECOMES OCCUPATIONAL MEDICINE

By action of the Board of Trustees of the American Medical Association the periodical known as *War Medicine*, published under the joint auspices of the American Medical Association and the Division of Medical Sciences of the National Research Council, will be discontinued with the issue for December 1945. In its place the Board of Trustees has authorized the publication of the periodical to be known as *Occupational Medicine*, designed to serve advancement in the field of prevention and treatment of disease conditions occurring to workers in every type of occupation and industry. An editorial board is in process of selection and will be announced just as soon as the Board of Trustees has taken action and those invited to serve have accepted the appointments. *Occupational Medicine* will not be the specific organ of any association or group, although it will have the advantage of material developed through the Council on Industrial Health of the American Med-

ical Association. Several members of the Council on Industrial Health have already consented to become members of the editorial board of the new periodical. In general makeup the new publication will include, as do the other specialistic periodicals published by the Association, original contributions, even of monographic scope, covering causes, diagnosis, pathology, prevention, treatment and indeed every phase of disease related to occupation. Included also will be new investigations concerned with work of personnel departments in industry, such as the effects of emotions, boredom and other psychologic problems. The utilization of mass technics in roentgenology for the detection of tuberculosis, the preplacement examinations designed to adapt the job to the physiologic condition of the worker, the causes of absenteeism and the use of occupation for rehabilitation of the handicapped are further examples of subjects to be considered. *Occupational Medicine* will also include abstracts of the important current medical literature related to occupational health and disease, also occasional editorials, book reviews, news and selected collective reviews on topics of current interest.

FOREIGN MARKETS AND AMERICAN DRUGS

A manual entitled "Medicinal Products—United States Equivalents and Alternatives," recently released by the Department of Commerce, presents in Spanish and Portuguese the American equivalents and alternatives for German medicinal products. The document lists in tabulated form the names under which the preparations are sold in Latin American countries, their composition, equivalents and alternatives in the United States and U. S. manufacturers and suppliers. Included are biologics, alkaloids and other chemicals, as well as vitamins, glandular products and many specialties. The information is of value to interested physicians and other scientists and to the drug and pharmaceutical industry. The American drug industry is becoming increasingly aware of the role it can assume in extension of American medicine to other nations. Those who believed Germany held chemical superiority in the Spanish Americas will be surprised to learn of the influence exerted by the drug industry of the United States. The purpose of the manual is to permit the profession in Latin America to become aware of the availability of medicinal products, their brand names and manufacturing sources, or the equivalent alternative available in the United States. Copies of the manual may be obtained from the Superintendent of Documents, Washington 25, D. C., or from any Department of Commerce field office at 50 cents each. The chief of the Drugs and Pharmaceuticals Unit, Bureau of Foreign and Domestic Commerce of the Department of Commerce, who was primarily responsible for the accumulation of the information in the manual, has emphasized elsewhere¹ the possibilities in foreign drug markets. He insists that a \$100,000,000 postwar foreign outlet is feasible and he believes that more firms could and should share in this market.

BED REST IN TUBERCULOSIS

Since Dock¹ emphasized that prolonged rest in bed during illness is not always salutary, numerous writers have critically examined the indications and contraindications in various diseases. Tuberculosis, the disease in which prolonged bed rest has been the remedy *par excellence*, has apparently received little consideration in these discussions. Now Peck and Willis² have evaluated bed rest in the treatment of tuberculosis. An analysis of 751 consecutive necropsies indicates the relative insignificance of the one great danger stressed for bed rest, namely pulmonary embolism. The evils that inhere in bed rest, Peck and Willis believe, are in its misapplication. If the diseased area is accurately localized, especially if cavity is present, and if the bedfast patient lies at intervals throughout the day in comfortable but proper postures for facilitating drainage, secretions are raised with a minimum of cough or without cough; thus the most potent cause of intracanalicular spread is abolished. Inherent in the success of bed rest as therapy is recognition of the emotional maladjustment of the average new and long term patient. When the physician understands the needs of the patient and is willing to take the time to explain and repeat and convince the patient of the value of the scheme, the success of such treatment is greatly enhanced. Bed rest, to be successful, must be correlated properly with collapse therapy. Good bed rest "is a precise method of treatment with clearcut specifications and is based on three fundamental principles: mental repose, muscular relaxation and adequate drainage."

NBC BROADCASTS RESUMED

On page 817 in this issue of THE JOURNAL appears a notice of the resumption of network broadcasting by the American Medical Association in cooperation with the National Broadcasting Company over the networks of the latter and affiliated stations. This will be the eleventh consecutive year of nationwide dramatized health broadcasts on the NBC networks. The dramatized broadcasts were preceded by two years of radio talks on the same networks. The American Medical Association has broadcast continuously since 1923, using various Chicago stations and several networks. Broadcasts have sometimes been as frequent as twice a day, but experience has shown that once a week, except during special events such as annual meetings, is sufficient. During this time numerous local broadcasts by state and county medical societies have been carried out. The American Medical Association Bureau of Health Education acts as a clearing house for assembling, editing and redistributing radio talks originated locally so that the best of these talks are made available throughout the nation. In 1943 the Bureau began a program of electrical transcriptions, of which there are now seventy-five programs available and additional ones in preparation; these transcriptions are estimated to be on the air an average of eighty-five or more times weekly. This coverage by radio represents not only an impor-

tant phase of health education of the public but also a large contribution from the broadcasting industry to public welfare. The time made available for these broadcasts has been furnished gratis on the theory that the station provides the facilities and the medical profession the materials for a joint public service in accordance with the provisions of the Federal Communications Act under which radio stations are obliged to broadcast "in the public interest, convenience and necessity." The cooperation by radio in health education has gone beyond what radio might reasonably have considered its obligations and has constituted genuine and valuable cooperation which the public should appreciate. Medical men and other scientists have been sharply critical of radio as, indeed, they have been of the press and other advertising mediums for the dissemination of false and misleading advertising of a medical and health character. Radio, often subjected to criticism, should also be given due credit for the contributions it has made to the cause of health education.

EFFECT OF STREPTOMYCIN ON BACTERIA IN URINARY INFECTIONS

Helmholz¹ points out that the sulfonamide compounds, while effective against most bacteria found in urinary infections, are ineffective against *Streptococcus fecalis* and *Pseudomonas aeruginosa*. Waksman and his associates showed that streptomycin has strong bactericidal action on both gram negative and gram positive bacteria, including *Pseudomonas aeruginosa*. Elias and Durso have shown that streptomycin given by the intravenous or intramuscular route is excreted in high concentration in the urine. Helmholz performed experiments in vitro with urine from a patient who had been receiving 2,000,000 units daily of streptomycin for weeks. This urine contained as high as 1,330 units of streptomycin per cubic centimeter. The urine was Seitz filtered and controlled for sterility. The amount of drug carried over in 0.5 cc. of urine when diluted ten times in 5 cc. of agar was sufficient to prevent the development of any colonies on the plates made immediately after the inoculation of urine. The use of 100 units of streptomycin per cubic centimeter of urine with inoculations of fewer than 2,000 bacteria per 0.5 cc. results in complete sterilization in twenty-four hours. The undiluted urine killed the two most resistant bacteria, two strains of *Streptococcus fecalis* and *Pseudomonas aeruginosa*, one hour after inoculation. Helmholz concludes that 100 units per cubic centimeter of streptomycin is probably sufficient to reduce rapidly the number of any bacteria found in urinary infections and that 235 units, which is only about one fifth of the concentration that can be obtained in the urine, is sufficient even with massive inoculation to sterilize the infected urine. At concentrations of 1,330 units per cubic centimeter the two most resistant bacteria are killed within one hour. In view of these results, Helmholz believes that streptomycin should prove to be the most useful urinary antiseptic so far developed.

MEDICINE AND THE WAR

ARMY

PROGRAM FOR DEFERRED RESIDENTS OF MEDICAL CORPS

Following is the modification of the program for deferred residents of the Medical Corps, published recently in War Department Circular No. 296, which will be effective until March 28, 1947 unless sooner rescinded or superseded:

1. **GENERAL AND ELIGIBILITY.** a. Medical Corps officers on active duty as explained below are eligible for release from active duty to accept residencies or fellowships in civilian hospitals. Upon their release, they must be replaced by a Medical Corps officer now on inactive duty and serving as a resident or fellow in the hospital to which the officer being released will report for postgraduate training.

b. **Criteria for eligibility:**

- (1) Must have been on active duty prior to Jan. 1, 1943.
- (2) Must be under 40 years of age.
- (3) Must not be eligible for release from active duty under other War Department directives or army regulations.

2. **APPLICATIONS** Procedure for filing

a. Application for determination of eligibility for release should be addressed to the Adjutant General (Attention Officers' Branch, Separation Section, Munitions Building, Washington, D. C.) through military channels. Application should be accompanied by a true copy of WD AGO form 178 2 or 66 3 in duplicate with a 2 by 2 inch passport type photograph attached.

b. A statement must accompany the application indicating that the criteria mentioned in paragraph 1 b apply. In addition the following information must be furnished.

- (1) Name of hospital in which residency or fellowship is desired. In this connection, first consideration should be given to applying for a residency or fellowship in the hospital in which the officer received his original training if the hospital has Medical Corps officers on an inactive status serving as residents or fellows.
- (2) A second and third choice of hospital will be given.
- (3) In the event applicant has already received an appointment from a hospital this fact will be clearly stated, giving the date the appointment was received, the type of residency or fellowship and the period of time during which the appointment will be effective.
- (4) No hospital should be named which does not have Medical Corps officers on an inactive status serving as residents or fellows.

3. **FORWARDING OF APPLICATIONS** a. All applications will be forwarded through military channels to the Adjutant General (Attention Officers' Branch, Separation Section, Munitions Building, Washington, D. C.) for forwarding to the Surgeon General regardless of whether the application is approved or disapproved by forwarding commander.

b. The first forwarding endorsement will include the following statements:

- (1) Approval or disapproval.
- (2) There is (or is not) an overall surplus in the command jurisdiction of officers qualified and available to fill the duty assignments for which the officer concerned is qualified.
- (3) A replacement will (or will not) be required and is (or is not) readily available.
- (4) Services of the officer have been such as to entitle him to separation under honorable conditions.
- (5) No disciplinary action or reclassification proceedings under AR 605-230 are pending or appropriate in the case.
- (6) No hospital disposition board or Army retiring board proceedings are pending or believed to be appropriate.

c. Subsequent forwarding endorsements will include statements of approval or disapproval and such other remarks as may be deemed pertinent.

4. **ACTION OF THE SURGEON GENERAL'S OFFICE AND PROCUREMENT AND ASSIGNMENT SERVICE, WAR MANPOWER COMMISSION.** a. Upon receipt and approval of the application by the Surgeon General, the application will be noted and forwarded to the Procurement and Assignment Service, War Manpower Commission, which service will act as intermediary agent between the War Department and the civilian hospital. The approval or disapproval of the application by the civilian hospital will be returned to the Surgeon General through the Procurement and Assignment Service, the Surgeon General through the name of a Medical Corps officer on inactive duty, who will be released by the hospital for active military service.

b. Upon receipt of an approved application from the Procurement and Assignment Service, War Manpower Commission, the Surgeon General will forward the papers to the Adjutant General (Attention Officers' Branch, Separation Section, Munitions Building, Washington, D. C.) giving the date the separation is to become effective and concurrently advise the applicant through military channels of the approval of the application and the date the applicant will be released from duty.

c. Concurrently with action taken in b above, the Surgeon General will request that orders be issued assigning the Medical Corps officer who is serving as a resident or fellow on an inactive status to active duty. The effective date of active duty will be ten days later than the date at which medical officer released from active service will report to the hospital.

CONVENTION HELD AT SCHOOL OF AVIATION MEDICINE

The Army Air Force School of Aviation Medicine, Randolph Field, Texas, was the scene of part of the Texas Surgical Society's two day convention in San Antonio recently. The program included a series of lectures and discussions by members of the AAF School of Aviation Medicine staff, an exhibit of specialized air force equipment and medical drawings of surgical techniques. Col. Fratis L. Duff, assistant commandant, opened the afternoon's schedule with a discussion of the activities of the AAF School of Aviation Medicine during the war. A paper on the research program and problems was presented by Major Herman S. Wigodsky, acting director of research.

"Experimental Production of Injuries by Deceleration" was the topic of a film-lecture given by Capt. Harry D. Kingsley. Major George M. Hass, chief of the department of pathology, addressed the society on the nature of injuries to personnel in aircraft accidents.

Major Randolph L. Clark Jr., under whose direction the program was planned, explained the surgical services of the AAF School of Aviation Medicine and illustrated his remarks with reproductions of medical photographs used in the teaching of aviation medical examiners. Cooperating with Major Clark in organizing the school's role in the conference was the society's secretary, Dr. Walter Stuck, San Antonio, Texas.

FORTY-NINTH FIELD HOSPITAL COMMENDED

The 49th Field Hospital, commanded by Major Thomas LaBarbera, Brooklyn, was recently awarded the Meritorious Service Unit Plaque "for superior performance of duty in the accomplishment of exceptionally difficult tasks during the period of Jan. 1 to May 8, 1945." The 49th gave medical and surgical support to the 66th Infantry division besieging the heavily defended ports of St. Nazaire and Lorient, Brittany, France. Functioning under arduous field conditions, the unit brought on the spot definitive treatment that saved hundreds of lives. Doctors, nurses and corpsmen worked seven days, and working days frequently ran into twenty-four hours. The hospital was under constant threat of German artillery fire. During this mission the unit was compelled to move 5 miles to the rear while continuing full capacity treatment of battle casualties. The unit is now operating station hospitals at the Calais Staging Area, Marseilles, and at Lyons, France.

APPOINTED HONORARY CONSULTANT TO THE SURGEON GENERAL

Comdr. Arnold F. Emeh, who recently was placed on inactive duty after three years as special assistant to the Surgeon General and chief of the Administration Division of the Bureau of Medicine and Surgery, has been appointed honorary consultant to the Surgeon General and to the Secretary of the Navy. Vice Admiral Ross T. McIntire, Surgeon General of the Navy, expressed his satisfaction in having Dr. Emeh available for management consultation in view of his exceptional services to him and to the Navy Medical Department.

PLAQUE AWARDED TO 381st STATION HOSPITAL

The 381st Station Hospital was recently awarded the Meritorious Service Unit Plaque for superior performance of exceptionally difficult tasks during the period July 6, 1945 to Sept. 25, 1945. The hospital is under the command of Lieut. Col. H. B. Hermann, New York; Major W. R. Carman, Islip, Long Island, chief of medical service, and Major Harry Martz, Birmingham, Ala., chief of surgical service.

PHYSICIANS SEPARATED FROM SERVICE

ARMY MEDICAL CORPS OFFICERS RECOMMENDED FOR/OR RELIEVED FROM ACTIVE DUTY

Alabama

Barfield-Carter, M., Major, 805 Woodward Bldg., Birmingham.
Donald, Joseph M., Lt. Col., 2900 Surrey Rd., Birmingham.
Douglas, Joseph W., Capt., Brewton.
Dunning, Guy J. Jr., Capt., Linden.
Hendrix, Richard W., Lt. Col., MacMillan St., Evergreen.
Holler, Carl A. F., Capt., Box 190, Fort Payne.
Johnson, George E., Major, Uriah.
Lanc, Thomas H., Capt., T. C. I. Hosp., Fairfield.
Lary, John H., Major, 407 Madison St., Huntsville.
Linn, Julius E., Major, 2909 Thornhill Rd., Birmingham.
McGraw, Felix J., Major, 1 S. 55th Pl., Birmingham.
Martin, John A., Lt. Col., 119 Gilmer Ave., Montgomery.
Meigs, James H., Major, 1209 Glenwood Terrace, Anniston.
Parker, Harry J., Capt., Madison.
Peterson, Edward J., Capt., St. Vincent's Hosp., Birmingham.
Timberlake, Landon, Major, 2121 Highland Ave., Birmingham.
Woodall, Paul S., Lt. Col., 201 Mount Ave., Birmingham.
Woodruff, Gerald G., Lt. Col., 620 Highland Ave., Anniston.

Arizona

Born, Ernest A., Capt., 310 S. Mount Vernon, Prescott.
Hinton, Joseph H., Capt., Fort Thomas.
Ketcherside, H. D., Major, 1006 Professional Bldg., Phoenix.

Arkansas

Anderson, Powhattan R., Capt., 1923 Main St., Little Rock.
Champion, Walton T., Major, Gillett.
Dunaway, Edwin L., Major, 1712 Scott, Conway.
Mack, Joseph J., Col., Little Rock.
Patton, Doyle L., Capt., 530 W. Block, Eldorado.
Smith, James T., Capt., P. O. Box 276, Paris.
Verser, Joe, Capt., Harrisburg.

California

Antonini, Charles J., Capt., 1413 38th Ave., San Francisco.
Asher, Leonard M., Major, 1901 Fairburn Ave., Los Angeles.
Badami, Anthony G., Capt., 1086 Canine Pablo, San Jose.
Brock, Burton K., 1st Lt., 236 Michigan Ave., Fresno.
Cawley, John J. Jr., Capt., 2003 Lester, Bakersfield.
Cecil, James J., Major, Patton State Hosp., Patton.
Chernow, Marvin L., Major, 3752 Woolwine Dr., Los Angeles.
Crowley, Francis L., Major, 519 Monte Vista Ave., Oakland.
Duncan, John J., Capt., 11123 Ophir Dr., Los Angeles.
Elliot, James S., Major, 1019 Hampshire St., San Francisco.
Elzey, Neil D., Capt., 1353 2d Ave., San Francisco.
Faier, Herman I., Major, 1930 Wilshire Blvd., Los Angeles.
Falk, Charles C. Jr., Major, 507 F St., Eureka.
Ferris, George J., Capt., 1588 35th Ave., San Francisco.
Haskell, Maurice M., Major, 1501 Pioneer Blvd., Artesia.
Hoffman, Ralph L., Capt., 3661 Pringle St., San Diego.
Houloose, James, Major, 3982 Gaviota Ave., Long Beach.
Hrenoff, A. K., Major, 2102 Golden Gate Ave., San Francisco.
Jacobus, W. L. Jr., Lt. Col., 3757 Hepburn Ave., Los Angeles.
Lim, Kwong, Capt., 1243 Minnesota St., San Francisco.
McClintock, Charles H., Capt., 5142 Escalon Ave., Los Angeles.
McCreary, J. H., Capt., 901 S. Kingsley, Los Angeles.
McCulloch, Robert J., Capt., 57 St. Joseph Ave., Long Beach.
Marchus, Donald B., Lt. Col., 1726 Market St., Redding.
Marks, Joseph H., Capt., 4340 Leimert Blvd., Los Angeles.
Marquis, Harold H., Major, 97 San Pablo Ave., San Francisco.
Maximov, N. G., Major, 2710 California St., San Francisco.
Mourer, Lyle A., Major, 5218 Angeles Vista Blvd., Los Angeles.
Ogden, Roderick A., Major, 2824 Park Way, Bakersfield.
Palmer, Alfred M., Capt., 625 Scott St., San Francisco.
Phetteplace, Dale O., Major, 806 N. Spadra Rd., Fullerton.
Reynolds, Stephen, Major, 230 El Bosque Rd., Santa Barbara.
Rose, Sidney J., Capt., 1520 E. Firestone Blvd., Los Angeles.
Rovane, John W., Capt., Yolo County Hosp., Woodland.
Schade, Frank F., Col., 1800 W. 6th St., Los Angeles.
Schmidt, Allen R., Capt., 2007 Wilshire Blvd., Los Angeles.
Schroeder, Ralph L., Capt., 443 Geronia, San Gabriel.
Schuldburg, Irving I., Capt., 6509 Hayes Dr., Los Angeles.
Schureman, Oliver P., Capt., 1307 Stradford Ave., Pasadena.
Spencer, James A., Capt., 2280 Pacific Ave., San Francisco.
Stansbury, John R., Capt., General Hosp., Santa Barbara.
Sweet, Norman J., Major, U. of Calif. Hosp., San Francisco.
Topic, John R., Capt., 312 Broad St., Nevada City.
Walker, Ralph J., Lt. Col., 4265 Atlas Ave., Oakland.
Weizer, Ernest A., Major, P. O. Box 831, Oakdale.
Wilmes, Malcolm N., Major, 523 Bartlett Ave., Woodland.
Wyborne, Eugene H., Capt., Riverside Co. Hosp., Arlington.

Colorado

Bradley, John W., Major, 2212 Wood Ave., Colorado Springs.
Brethower, Norman A., Capt., 606 S. 2d St., Montrose.
Fee, Edward P., Capt., 533 Ralson, Arvada.
Hick, Lawrence L., Major, Delta.
Ralston, Robert J., Capt., Holyoke.

Connecticut

Chipman, Sidney S., Major, 6 Stevens St., Norwalk.
Conway, Herbert, Lt. Col., 225 Ocean Dr. West, Stamford.
Friedman, Emerick, Capt., Norwich State Hosp., Norwich.
Goldschmidt, Myer, Capt., 10 Grove Hill, New Britain.
Haas, William R., Col., 789 Howard Ave., New Haven.
Krosnick, Gerald, Major, 574 Elm St., New Haven.
Meyers, Royal A., Major, 162 Main St., Watertown.
Rogers, Robert P., Lt. Col., 111 North St., Greenwich.
Scoville, William B., Major, 334 N. Steele Rd., W. Hartford.
Simmes, John P., Capt., 446 Stratfield Rd., Bridgeport.
Slater, Daniel, Capt., 1100 Dixwell Ave., Hamden.
Smith, William B., Lt. Col., 91 Center St., Wethersfield.
Sollosy, Alexander, Capt., 365 McKinley Ave., Bridgeport.
Unsworth, Arthur C., Lt. Col., 179 Allyn St., Hartford.

Idaho

Bovenmyer, Earl S., Major, 243 E. 6th St., Pocatello.
Durose, Fred W., Capt., P.O. Box 172, Bonners Ferry.
Guyett, Harvey E., Capt., 562 Jay St., Idaho Falls.
Holstein, Theodore, Capt., Route 2, Boise.
Hunter, Lewis B., Capt., 111 Bank St., Wallace.
Rulien, Ward A., Major, Wendell.
Schow, Floyd W., Major, Hailey, Blaine County.
Van Dorn, Robert W., Major, Cocur D'Alene.
Wendle, Cornelius C., Major, Sandpoint.

Illinois

Droegenueuer, William H., Major, 116 Burnham Pl., Evanston.
Ellwood, Walter W., Lt. Col., 1525 E. 53d St., Chicago.
Epstein, Jacob M., Capt., 5404 S. Woodlawn Ave., Chicago.
Farinacci, Maurice G., Capt., 5519 S. Tolman, Chicago.
Giganti, James J., Capt., 2614 Iowa St., Chicago.
Ginsberg, Robert S., Capt., 5220 Drexel Blvd., Chicago.
Golden, Jacob S., Capt., 531 Briar Pl., Chicago.
Goodhart, Jacob A., Capt., 6557 Francisco Ave., Chicago.
Graham, John P., 1st Lt., Avon.
Herron, Earl, Major, 162 E. Ohio St., Chicago.
Hirsh, Edwin L., Capt., 3658 N. Pinegrove Ave., Chicago.
Hoffman, Samuel J., Lt. Col., 3800 Lake Shore Dr., Chicago.
Holvey, Ervin H., Capt., 347 So. Harvey St., Oak Park.
Hornung, V. H. H., Capt., 1752 New England Ave., Chicago.
Hume, Albert T., Major, 400 E. Washington St., Monticello.
Jakubowski, Casimir L., Capt., 1324 N. Ashland Ave., Chicago.
Johnson, Lowell R., Capt., 1424 N. Oak St., Danville.
Knowles, Donald B., Capt., 7409 Clyde Ave., Chicago.
Koenigsberg, Noah M., Major, Bellflower.
Kudolla, Charles R., Capt., 4958 Lawrence Ave., Chicago.
Lampert, Elmer G., Capt., 625 S. Wheaton Ave., Wheaton.
Larrabee, John A., Capt., 5724 Harper Ave., Chicago.
Lemberg, Louis, Capt., 2900 W. Fitch Ave., Chicago.
Luke, Edward A., Major, 710 Center St., Waukegan.
McDowell, Mordecai M., Major, 1207 E. Main St., Danville.
Mannroser, Lambert F., Capt., 6127 NW Hwy, Chicago.
Mason, John C., Capt., 109 N. Chicago, Rossview.
Millas, John G., 1st Lt., 1607 S. 51st Ave., Cicero.
Mizeck, Albert A., Capt., 3952 W. Jackson Blvd., Chicago.
Motier, Jean H., Capt., 7427 S. Wentworth Ave., Chicago.
Mullen, Timothy F., Lt. Col., Seneca.
Musick, Rowland H., Capt., 904 14th Ave., Mendota.
Nash, John V., Major, 5412 Ferdinand St., Chicago.
Nelson, Clayton, E. J., Capt., 3822 N. Hoyne Ave., Chicago.
Partridge, Milton H., Capt., 666 St. John St., Elgin.
Pilot, Isadore, Major, 507 Briar Pl., Chicago.
Post, John, Lt. Col., 5811 Dorchester Ave., Chicago.
Puestow, Charles B., Col., 874 Ridgewood Dr., Highland Park.
Raney, Alden B., Capt., 232 S. Euclid Ave., Oak Park.
Reierson, Peter A., Major, 1336 S. Newberry St., Chicago.
Schoolman, Joseph G., Capt., 4742 Ingleside Ave., Chicago.
Stephen, Robert J., Capt., 15 N. Cagwin Ave., Joliet.
Stephenson, George W., Major, 1516 E. Grove St., Bloomington.
Stuart, Carroll W., Major, 330 N. Austin Blvd., Oak Park.
Sutton, Robert M., Major, 107 Moss Ave., Peoria.
Sweeney, Anthony J. Jr., Major, 1770 Arthur Ave., Chicago.
Taylor, James H., Capt., 200 Heaton St., Villa Grove.

Hall, John B., Capt., 235 Hallock St., Jamestown.
Hamill, John A. C., Major, 55 Hillcrest Ave., Port Chester.
Hamilton, George C., Lt. Col., 537 Chenango St., Binghamton.
Hartstein, A. S., Capt., 61-80 80th St., Elmhurst, Queens.
Heath, F. K., Major, The Meadows, S. Road, Poughkeepsie.
Horan, William H., Capt., 9 Pickwick Rd., Manhasset.
Horne, Robert P., Capt., Skaneateles.
Horowitz, Isaac, Capt., 314 E. 193d St., Bronx.
Horowitz, Jacob, Capt., 143 W. 49th St., New York.
Howes, Clifford Eggleston, 1st Lt., Rocky Point, Long Island.
Iraci, Joseph P., Capt., 5444 101 St., Corona.
Ittri, Francis V., 1st Lt., 2383 83d St., Brooklyn.
Ittleman, Felix L., Major, 888 Montgomery St., Brooklyn.
Jacobs, Theodore T., Major, 100 High St., Buffalo.
Jacobs, Thomas P., Capt., 280 Beechmont Drive, New Rochelle.
Judelsohn, Louis, Major, 75 Fordham Drive, Buffalo.
Kaplan, Bernard I., Capt., 67 South Highland Ave., Ossining.
Katz, Abraham, Capt., 335 Cypress Ave., Bronx.
Kaywin, Louis, Capt., 71 St. Marks Pl., New York.
Klein, Daniel, Major, 3689 Bedford Ave., Brooklyn.
Konigsberg, Max S., Capt., 237 W. 233d St., New York.
Langsam, Sanford M., Capt., 1415 Motte Ave., Far Rockaway.
Lear, Phillip E., Major, 1240 E. 26th St., Brooklyn.
Leffert, Jacob, Capt., 10 Argyle Rd., Brooklyn.
Levin, Thomas, Major, 2325 University Ave., New York.
Leonidoff, Aleksei A., Col., Pendell Rd., Poughkeepsie.
Leslie, Robert J., Major, 2620 Glenwood Rd., Brooklyn.
Letterese, Thomas G., 1st Lt., 2319 Grotona Ave., New York.
Levine, William, Capt., 754 Brady Ave., Bronx.
Levy, Jacob, Capt., 336 E. 91st St., Brooklyn.
Levy, Sidney, Capt., 1020 E. 16th St., Brooklyn.
Lewis, Ned A., Lt. Col., 53 Linden St., Brooklyn.
Liepmann, Hans W., Capt., Spring St., Monroce.
Lo Ponte, Joseph J., Capt., 2020 E. 3d St., Brooklyn.
McManus, Matthew P., Capt., 219-16 43d Ave., Bayside.
McMillan, James R., Capt., 303 East 20th St., New York.
McNeer, Gordon, Major, 644 Riverside Dr., New York.
Manganelli, Charles V., Major, 26 W. 61st St., New York.
Mangiaracina, C. C., Capt., 88-04 Woodhaven Blvd., Woodhaven.
Mansker, Joseph S., Capt., 2075 Wallace Ave., Bronx.
Marks, Jerome L., Major, Beth Israel Hosp., Stuyvesant Park, East New York.
Mele, Joseph M., Capt., 619 Jay St., Rochester.
Melton, Joseph, Capt., 1810 Nereid Ave., Bronx.
Meneely, John K. Jr., Major, Coeymans.
Myer, Clifton G., Major, 34 Catherine St., Lyons.
Oliva, Joseph J., Capt., 2901 170 St., Flushing.
Parise, Nicholas F., Capt., 10 Washington St., Brooklyn.
Pender, Patrick F., Capt., 2114 Genesee St., Utica.
Perillo, Louis A., Capt., 1927 Pilgrim Ave., New York.
Perl, Theodore, Capt., 225 Squires Ave., Endicott.
Piacentine, Pasquale A., Capt., 39-20 62d St., Woodside.
Pisani, Bernard J., Lt. Col., 130 E. 67th St., New York.
Porrizzo, Andrew P., Major, 366 Clinton St., Brooklyn.
Province, William D., Major, 622 W. 168th St., New York.
Rautenstrauch, Walter Jr., Major, 42-15 220th St., Bayside.
Roberts, Alfred E., Capt., Main St., Portland.
Romano, Michale J., Capt., 114 School St., Yonkers.
Rosner, Henry, Capt., 4824 Ave. I, Brooklyn.
Reid, Henry N., Capt., 1413 N. Madison St., Rome.
Rubbone, Mario D., Capt., 31-41 28th Rd., Long Island.
Rubin, Julius, Capt., 439 Sackman St., Brooklyn.
Rudner, Nathan, Capt., 3511 Putnam Pl., Bronx.
Ryan, David F., Capt., 61 Hildreth Pl., Yonkers.
Sachs, Elihu M., Major, 98 Riverside Dr., New York.
Schellenger, E. A. Y., Major, 33 Fifth Ave., Merchantville.
Schnittke, Sidney, Capt., 270 Convent Ave., New York.
Schussheim, Joseph, Capt., 3051 Ocean Ave., Brooklyn.
Senfeld, Sidney, Capt., 2122 Quentin Rd., Brooklyn.
Silvera, Salomon, Major, 7524 Bay Parkway, Brooklyn.
Smith, Harold B., Capt., 126 Rugby Road, Syracuse.
Smith, Joel F., Capt., 1799 Bedford Ave., Brooklyn.
Spinard, Walter I., 1st Lt., 143 Keap St., Brooklyn.
Sprei, Emanuel, Capt., 143 West 96th St., New York.
Spritzer, Irwin I., Capt., 1414 E. 12th, Brooklyn.
Stagnitto, Rosario J., Capt., 482 Hawley St., Rochester.
Strutton, William R., Major, Rockland St. Hosp., Orangeburg.
Thompson, James B., Capt., Gen. Hosp., Rochester.
Vandow, Jules E., Capt., 339 E. 58th St., New York City.
Van Wagenen, William P., Lt. Col., Fishell Road, Rush.
Warres, Herbert L., Capt., 1987 Ocean Parkway, Brooklyn.
Zimmerman, Louis, Major, 340 St. Johns Pl., Brooklyn.

ORGANIZATION SECTION

Postwar Medical Service

MEETING OF SEPTEMBER 22

The meeting of the Committee on Postwar Medical Service was called to order by the Chairman, Dr. Ernest E. Irons, in the Board of Trustees Room of the American Medical Association Building at 10 a. m. Saturday, September 22. The following members, liaison members and guests were present:

Dr. Irvin Abell.	Col. B. R. Kirklin.
Dr. Louis H. Bauer.	Dr. Herman L. Kretschmer.
Lieut. Col. Robert D. Bickel.	Dr. Roger I. Lee.
Dr. Walter L. Biering.	Major Gen. George F. Lull.
Dr. Francis G. Blake.	Col. Hugo Mella.
Dr. Frederick A. Collier.	Dr. J. J. Moore.
Mr. Graham L. Davis.	Dr. Walter W. Palmer.
Major Gen. Warren F. Draper.	Dr. Carl M. Peterson.
Capt. William E. Eaton.	Lieut. Col. William N. Piper.
Lieut. Col. Bryan C. T. Fenton.	Father Alphonse M. Schwitalla, S.J.
Dr. Morris Fishbein.	Dr. R. L. Sensenich.
Major Gen. Paul R. Hawley.	Dr. H. H. Shoulders.
Dr. E. L. Henderson.	Dr. LeRoy H. Sloan.
Mr. Thomas A. Hendricks.	Dr. Austin E. Smith.
Mr. J. W. Holloway Jr.	Mr. Barry C. Smith.
Dr. Ernest E. Irons.	Miss Mary Switzer.
Dr. Victor Johnson.	Dr. Olin West.
Dr. Edwin P. Jordan.	Dr. Fred C. Zapffe.

The minutes of the meeting held on June 23, 1945, were approved.

The Chairman presented the regrets of Dr. Evarts A. Graham, Dr. Arthur W. Allen and Dr. James E. Paullin that they were unable to attend the meeting. Major Gen. Warren F. Draper, Deputy Surgeon General of the U. S. Public Health Service, who had been on overseas duty for the past year, resumed his place as a member of the Committee, and he, Dr. Roger I. Lee, President-Elect of the American Medical Association, who served as first chairman of the Committee, and Major Gen. Paul R. Hawley, recently appointed as head of the Medical Department of the Veterans' Administration, were welcomed.

A letter of resignation as liaison member of the Committee between the Office of the Surgeon General of the Army and the American Medical Association was presented from Lieut. Col. Harold C. Luth. Colonel Luth's resignation was accepted with regret and with appreciation of his services. It was announced that Lieutenant Colonel Piper would henceforth represent the Personnel Service of the Surgeon General's Office.

BUREAU OF INFORMATION

Lieut. Col. Robert D. Bickel, Liaison Officer, presented the following report:

The main energies of the Bureau of Information recently have been exerted toward getting in hand completed county summary sheets from all the states and establishing a reporting system by means of which the summary sheets can be kept up to date. It also has been necessary to arrange a uniform system of handling correspondence, which is becoming increasingly heavy. Problems having to do with medical education and postgraduate training are being referred to Dr. F. H. Arestad of the Council on Medical Education and Hospitals and those dealing with licensure and other legal matters to Mr. J. W. Holloway Jr., Director of the Bureau of Legal Medicine and Legislation. Correspondence regarding locations or the establishment of a practice are answered by the Bureau of Information from material on file in the Bureau.

As of Sept. 1, 1945 the returns of county summary sheets were complete from twenty-four states, returns from twenty-one states were partially complete and no returns whatever had been received from four states. A total of 2,357 county summary sheets have been received, leaving 716 still outstanding. Every effort is made to insure the accuracy of all entries on the summary sheets, and when inquiries are received from medical officers duplicate sheets for the areas concerned are filled out and forwarded. It has been the consistent policy of the Bureau of Information in corresponding with officers of state medical societies to stress the fact that the Bureau is not a placement agency and has no desire to send physicians into any area or community where places are being held open for men still in service.

Information concerning areas in need of physicians and specialists is on file in the Bureau as well as are the names of specialists seeking locations. There is also a file of industrial positions available and a file

of pertinent current editorials and articles. In order that the data on file with respect to the distribution and need of physicians may be kept up to date an effort has been made to secure from each state medical society monthly listings of areas of need, and, in addition, a questionnaire has been mailed to each civilian physician in the country the return of which it is hoped will make possible the correction of existing data and will insure more accurate information.

An analysis of the correspondence received in the Bureau shows that, up to September 1, 213 physicians have written for information concerning locations in which to establish a practice; 85 communities or industries have requested help in finding a physician to relieve critical need; 110 communications have been received covering matters related to medical education, 81 pertaining to legal matters, and 65 completed county summary sheets have been given to office visitors.

The Information Bulletin for Medical Officers, which was presented to the Committee in galley form at the June meeting, has been distributed in the following manner: 50,000 copies were sent to the *Bulletin of the U. S. Army Medical Department*, 13,300 to the Bureau of Medicine and Surgery of the Navy and 1,800 to the Surgeon General of the U. S. Public Health Service. Approximately 3,000 copies have been sent to individuals, and as soon as shipping instructions are received 4,000 copies are to be forwarded to the Army Medical Library. The total number of copies printed was 76,100.

In reply to questions by Miss Switzer as to the number of medical officers who inquire about going into needy communities, Colonel Bickel stated that most of the inquiries were received from men who want to change locations and in doing so want to go where there are good hospital and laboratory facilities; they are not desirous of going into small rural communities where much travel would be necessary and good hospital facilities are lacking. Miss Switzer stated that the Procurement and Assignment Service is much concerned with the pressure from needy communities themselves, from Congress and others with respect to the maldistribution of physicians, which has almost reached crisis proportions; that an attempt should be made to work out a solution of the situation with the help of the state medical societies and state procurement and assignment committees, and that hospitals having available residencies should try to encourage the men coming back to practice—particularly the younger men—otherwise the maldistribution will be worse than it was during the war not only factually but from the point of view of public relations. Miss Switzer further stated that the South and some parts of the Middle West were most vitally concerned but that the communities most seriously in need of medical service were in Pennsylvania and perhaps in Indiana, and that a concerted effort to attract physicians to practice was being made by some of the Southern states through appropriation of money by state legislatures. Father Schwitalla asked what the Bureau of Information might be able to do in this matter, and Colonel Bickel replied that the plan of the Bureau has been to inform inquiring veterans as to where there is a need for a physician and to refer them to the state medical society concerned for further help, and that his contact had been mostly with men who do not expect to return to their former locations or had not been in practice before entering the armed forces and are anxious primarily to obtain certification by a specialty board before making definite plans for location and are determined to get such certification before doing anything else. Practically all of them want to obtain residencies at the more well known medical institutions; they don't want to go to the smaller hospitals, although a concentrated effort has been made through the Bureau of Information to tell such men where there is need for physicians to practice. The fact that the Bureau does not operate an actual placement service but works through local medical societies makes it difficult to do anything more than that.

Miss Switzer remarked that in many communities there seems to be great resistance on the part of the state and county societies to the admission of new men, this resistance seeming to stem from the idea that the places of men now in service should be kept open against their return.

Dr. West discussed the problem and stated that another matter having direct bearing on it was the almost insurmount-

able difficulty of securing office space in many of the larger cities and towns, and that the Editor of *THE JOURNAL* has it in mind to make an appeal to the profession generally through the columns of *THE JOURNAL* to share their office facilities with the returning officers until more office space is available.

The Chairman emphasized the point that the Bureau of Information is not meant to be and cannot be a placement bureau and that the states and counties have and should have the opportunity and the responsibility in the matter. Dr. Fishbein also contributed to the discussion, saying that the majority of the officers who would be released between now and June would be the older men, who would undoubtedly return to their former locations, and that it is the younger men who have never practiced who will want satisfactory residencies and continued education. Colonel Piper said that the separation plans now call for the automatic release of the older men and that the younger men would very likely be held in service a little longer. Colonel Bickel's opinion was that, since so many of the physicians in service want some training before going back to practice and so many are willing to practice if they can get their training, the most important thing to do is to concentrate on a residency and training program. A medical officer who has been doing only administrative work for a number of years is hesitant to meet competition without further training.

General Draper mentioned newspaper articles quoting Surg. Gen. Thomas Parran and Col. W. Paul Holbrook which would seem to have an important bearing on this problem if the suggestion for utilizing civilian hospitals and physicians in the care of veterans and the idea of establishing large, central hospitals with smaller hospitals and contingent facilities radiating therefrom should be adopted. Mr. Barry C. Smith, director of the Commonwealth Fund, told the Committee that the Commonwealth Fund had maintained for a long time a fellowship program whereby medical students were educated under an agreement that on completion of internships they would go to practice in rural communities, but that many of the men tended to avoid the very districts where they were most needed, a few failed to keep the agreement entirely and many left rural practice after the initial three year period. He thought this of interest in connection with a proposal that the Army be asked to release physicians on condition that they go to practice in needy communities.

The report on the Bureau of Information was accepted and publication authorized.

LOCAL PLANS FOR ASSISTANCE TO RETURNING MEDICAL OFFICERS

The Chairman announced that the Board of Trustees of the American Medical Association had authorized the acceptance for publication in *THE JOURNAL* free of charge of advertisements by medical officers seeking locations. (See *THE JOURNAL*, October 6, p. 450.)

Dr. Abell stated that in Louisville, Ky., a survey of available office space had been made, that some physicians had offered to share their own office space, that every full time and part time state and county health department and hospital staff opening was being noted, and that a fund to provide loans to returning medical officers if needed was being raised. Dr. West stated that the Medical Society of the State of Pennsylvania and several of the larger county medical societies are raising loan funds for veterans. Miss Switzer stated that the Kansas Medical Society had established such a fund. (Other medical associations that have made or are making definite plans along these lines are the Connecticut State Medical Society, which is setting up a Service Bureau; the Medical Society of Delaware; the Indiana State Medical Association; the Louisiana State Medical Society; the Massachusetts Medical Society, which has under consideration the establishment of a postwar loan fund; the Medical Society of the County of New York, which has formed a medical veterans' aid fund, and the Columbus, Ohio, Academy of Medicine with a veterans' collateral pool fund.)

EDUCATIONAL INTERSHIP AND RESIDENCY OPPORTUNITIES

Dr. Victor Johnson, Secretary of the Council on Medical Education and Hospitals, presented the following statement:

The Sept. 29, 1945 issue of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* will contain a revised list of residency places in approved hospitals. In this list there are approximately 2,000 approved residency

positions in excess of the numbers available in approved hospitals before the war. It is anticipated that there will be a great demand for this information, so that a large reprinting will be made. As hospitals continue to plan expansion in their residency offerings, the list of approved residencies will be revised. A large number of requests for information of this kind has been received in the headquarters of the Council on Medical Education and Hospitals. To facilitate supplying desired information, the Council is establishing with hospitals a reporting system by means of which data on existing vacancies will be kept up to date. The Council's publication of "Postgraduate Continuation Courses for Veteran and Civilian Physicians" has been widely sought by returning medical officers. Over 1,000 copies of this reprint have been distributed already, and another large reprinting has been made.

Colonel Fenton gave an outline of the training program in force in the regular Army. He said that the majority of the officers of the Army Medical Corps during the wartime period had been placed in administrative positions and that the Army now was attempting to train them for manning the Army hospitals so that the A. U. S. officers might be released to civilian life. He further stated that the Army had a more far reaching program which would provide further training for its regular Medical Corps officers looking toward certification by various specialty boards and that in this program the cooperation and help of the Committee on Postwar Medical Service and its cooperating members would be greatly appreciated. He stated further that a somewhat larger regular Medical Corps is expected to be maintained in the future, that the plan at the present time is for the integration of the A. U. S. officers all along the way, that if possible men over 40 years of age would not be included, that it is hoped the majority will be 35 or under, that present A. U. S. officers are constantly inquiring about getting into the regular Army Medical Corps and that the War Department is now working on a policy.

Dr. Johnson commented that all who have been concerned with providing educational opportunities for returning medical officers are greatly appreciative of the interest the Army and Navy has taken in the problem and that the task they are now attempting to carry through will assist civilian hospitals materially in providing what the men want.

Dr. Zapffe brought up the question of the difficulty encountered by medical officers who are graduates of unrecognized medical schools in getting into registered hospitals. Colonel Piper believed that there are about 400 officers who are graduates of unrecognized schools, and Dr. Johnson stated that nothing much could be done, since many of the states require that a resident physician in a hospital must be licensed to practice in the state. There was continued discussion, after which Dr. Johnson's report was approved and publication authorized.

ENROLMENT OF MEDICAL STUDENTS

The following report was presented by Dr. Victor Johnson:

The cessation of hostilities with Japan has not altered the position of the Selective Service System, the Army or the Navy regarding the deferment of qualified premedical students and the return of qualified men now on active duty in the Army or the Navy to continue premedical or medical studies. However, the Senate recently referred the Downey resolution (No. 134) to the Senate Military Affairs Committee. Among other things this resolution calls for an investigation into the supply of medical students in the immediate future. Col. W. Paul Holbrook of the Air Surgeon's Office has been secured by the Senate committee to conduct the investigation. Conferences and correspondence between Colonel Holbrook and the Secretary of the Council on Medical Education and Hospitals have taken place, and it is hoped that appropriate action along the two lines mentioned may be forthcoming. Such action is still necessary, even though hostilities have ceased, because inductions are continuing and the younger men will probably be the last to be discharged from active duty, so that the acuteness of the shortage of qualified medical students continues. At the request of the Inter-Agency Committee on Deferments, the Procurement and Assignment Service is also studying the question of the supply of premedical students. Should it be demonstrated that inadequate numbers of veterans will be available to fill the 1946 classes to peacetime capacity, the Inter-Agency Committee has indicated that it may reconsider its deferment policies.

In the ensuing discussion Miss Switzer stated that the Procurement and Assignment Service had made a great effort to secure the concurrence of Selective Service in the deferment of premedical students, that General Hershey feels that such students should be procured from the veteran group, that there is an interdepartmental committee which has the authority to say which men shall be deferred, that it finally was agreed that an attempt would be made through publicity and other means to acquaint Army and Navy men with the need for premedical students and to put the men in touch with the schools.

and that if there was no material improvement in the situation through these efforts the matter would come up again in October. Father Schwitalla mentioned that he had accepted appointment as a "premedical adviser" for the separation center at Jefferson Barracks, Missouri, and that the number of possible candidates for premedical study is extremely small.

Dr. Johnson's report was accepted and publication authorized.

SURPLUS MEDICAL AND HOSPITAL SUPPLIES

Father Schwitalla, Chairman of the Subcommittee on Surplus Medical and Hospital Supplies, requested Miss Switzer to make the report for the Subcommittee, which she did as follows:

Mr. Symington has been appointed Surplus Property Administrator, and a beginning seems to have been made. The Advisory Committee to the Administrator was appointed last week in the hope that it may be of assistance in setting up standards of need necessary for our guidance. The Surplus Property Board has transferred certain funds for planning an orderly procedure. Machinery will be needed to determine eligible claimants, price differentiation and areas of need. Both the Public Health Service and the Office of Education are assembling staffs which will be well under way within the next thirty days. The Administrator's office expects to coordinate the two and keep standards somewhat similar.

Four members of the Subcommittee on Surplus Medical and Hospital Supplies are members of the Advisory Committee, namely Dr. Irons, Dr. Tishbein, Father Schwitalla and Miss Switzer.

The organizations asked to name representatives on the Advisory Committee are the American Medical Association, the American Dental Association, the American Hospital Association, the American Public Health Association, the American Pharmaceutical Association and engineering groups. It probably will be felt that some representatives of industry will be needed. This is strictly a professional committee to rely on for suggestions as to standards, degrees of need, and so on.

The Chairman presented a letter addressed to the Secretary of the American Medical Association by Dr. A. S. Fernando of Manila, who is attempting to revive the Philippine Medical Association, of which he was secretary-treasurer for many years, and to rehabilitate the University of the Philippines, whose buildings were practically razed. (Dr. Fernando wrote that the library of the Philippine Medical Association was completely burned and that the Bureau of Science housing the Scientific Library, which was reputed to have the best and largest collection of medical publications in the Far East, is now only rubble and ashes.) Dr. Irons stated that the Board of Trustees of the American Medical Association had referred Dr. Fernando's communication to the Committee on Postwar Medical Service. What the Committee might do in the way of assistance to the medical profession in the Philippines was discussed at length, and the following statement was adopted for transmission through Miss Switzer to Hon. Paul V. McNutt, recently appointed High Commissioner to the Philippines.

The Committee on Postwar Medical Service wishes to extend to Hon. Paul V. McNutt in his capacity as High Commissioner to the Philippines its support for any program which he may develop for the use of surplus supplies or materials to help in the Philippine situation.

Miss Switzer was requested to report back to the Committee at its next meeting.

VETERANS ADMINISTRATION

The Chairman stated that the setup of the Veterans Administration had been changed since the subcommittee of the Committee on Postwar Medical Service had been at work, that General Hawley, present at this meeting, would have charge of the medical functions in the Administration, and that the Committee will be delighted to be of service to the Veterans Administration as it is now and as it will be constituted.

Father Schwitalla, chairman of the subcommittee dealing with the Veterans Administration, stated that General Hawley would present to the committee the modifications that have been recommended by the Veterans Administration and the outline, content, and so on of a new bill which might be called the Administration's own bill and which will undoubtedly mean the withdrawal of the old bills that provided for the organization of a medical corps in the Veterans Administration.

General Hawley then presented a concise outline of a bill being drawn for presentation to Congress providing for the reorganization of the Veterans Administration and made particular reference to certain sections having to do with a Department of Medicine and Surgery, as follows:

The bill provides for a Department of Medicine and Surgery to consist of an Office of the Surgeon General, a Medical Corps, Dental Corps and Nurse Corps and an Auxiliary Corps to provide for allied sciences.

It provides for a Surgeon General to be appointed by the President for a four year term, a Deputy Surgeon General and eight Assistant Surgeons General, one of whom shall be from the Dental Corps and will be chief of that corps. The Surgeon General shall be a qualified doctor of medicine. The Auxiliary Corps shall consist of pharmacists, physical therapists, dietitians, occupational therapists and other scientific personnel including bacteriologists, pathologists, chemists, biostatisticians and medical and dental technologists. The Auxiliary Corps shall further include non-commissioned personnel to be appointed without regard to civil service laws. The several corps shall each include a reserve corps.

All persons appointed in the Department of Medicine and Surgery must be citizens of the United States of America, and those appointed in the Medical Corps must be persons holding the degree of doctor of medicine from a college or university approved by the Administrator of Veterans' Affairs who have completed internships in an institution satisfactory to the Administrator and who have been licensed to practice medicine in one of the states or territories or in the District of Columbia.

The bill provides for promotion by length of service and examination. Grades below those of Surgeon General and Deputy and Assistant Surgeons General are comparable to Army grades from colonel down. Disciplinary boards to determine charges of ineptitude or misconduct are provided for. Within the restrictions imposed in the bill, the Surgeon General may rate any officer of the Department of Medicine and Surgery as a medical, surgical or auxiliary specialist. He may rate as specialists only those who are certified by an American specialty board. Any officer rated as a medical, surgical or auxiliary specialist shall receive 25 per cent higher pay. This is an incentive to do better work. Retirement pay is comparable with Army regulations.

The bill provides authority for the President to declare the Department of Medicine and Surgery a part of the military forces in time of war. It provides for medical and dental service for members themselves and, when available, for their dependents the same as in the Army and Navy, and it also provides for rotation of personnel into the Army and Navy for exchange of ideas and graduate instruction. The Administrator of Veterans' Affairs is authorized to place personnel on duty in schools of the Army, Navy and Public Health Service and in civilian institutions to increase knowledge. A broad section authorizes the Administrator to employ other personnel in addition to professional personnel, sets up a medical advisory council and gives it status under the law to advise the Administrator through the Surgeon General on medical policies.

After extended general discussion, in which it was brought out by Dr. Shoulders that the Committee on Postwar Medical Service had at its meeting held on March 17, 1945 endorsed the intent and provisions of the Rogers bill (H. R. 1661), the Committee voted to empower the subcommittee to withdraw the Committee's endorsement of the Rogers bill and to act on endorsement or nonendorsement of the new Veterans Administration bill described by General Hawley when it is presented to Congress. The consensus was that the bill as described by General Hawley would merit the complete support of the Committee on Postwar Medical Service and the medical profession generally.

Father Schwitalla offered a brief report for the Subcommittee to Confer and Cooperate with the Veterans Administration on Educational Opportunities for Veterans, stating that the Subcommittee hoped to see, before the next meeting of the whole Committee, Mr. H. V. Stirling, director of the Vocational Rehabilitation and Education Service, in order to obtain more information and statistics with respect to veterans who may be interested in acquiring a medical education and to determine, if possible, what is happening or will happen in the cases of veterans who serve as interns and residents in hospitals under the educational provisions of the G. I. bill with particular reference to those residents in hospitals that do not provide strong educational opportunities.

The Chairman stated that the Subcommittee to Confer and Cooperate with the Veterans Administration, consisting of Father Schwitalla and Dr. Collier, would be continued and a further report expected at the next meeting. He also said that the Subcommittee on Establishment of a Medical Corps in the Veterans Administration will be continued with the addition of Dr. Collier as a member.

DEMOBILIZATION OF MEDICAL OFFICERS

Dr. Collier, Chairman of the Subcommittee on Formulation of Lists of Medical Officers for Demobilization, requested General Lull to give the Committee such information as he could, and General Lull responded with the following statement: The machinery for discharge of medical officers is now working and a great many already have been discharged and returned to civil life, the bulk of the teachers requested by medical schools, if they were not overseas, have been discharged, those over 40 years of age or who entered service before Pearl Harbor will get out soon and the medical schools will have a very large

proportion of their teachers back before the first of the year—this is in addition to the normal demobilization; there will be excellent results in the next couple of months.

Dr Zapffe substantiated the statement of General Lull, further stating that medical schools do not seem to understand that the Army cannot release certain men it considers essential to its own needs. He also said that the Navy is working on lists of needed teachers now serving as Navy medical officers, and he was sure the matter is going forward as rapidly as possible.

Captain Eaton informed the Committee concerning a Navy Department directive covering discharge procedure for Navy officers, which became effective on September 15. He stated that most of the men requested by the medical schools are being released now as far as possible, particularly the ones in this country, and also those known as "hardship cases."

The Subcommittee was continued.

BUSH REPORT ON PROPOSED NATIONAL RESEARCH FOUNDATION

Dr Blake, Chairman of the Subcommittee to Study the Bush Report on a Proposed National Research Foundation, presented the Subcommittee's report. After discussion and amendment, the report was adopted and immediate publication authorized. (The report of the Subcommittee appeared in THE JOURNAL, October 6, p 466.)

WARTIME GRADUATE MEDICAL MEETINGS

The Chairman presented a letter from Dr F F Borzell, Chairman of the Central Committee of the Wartime Graduate Medical Meetings, in which it was stated that that committee had taken steps to terminate its activities on or before Dec 31, 1945, and the Chairman announced that the three organizations sponsoring the meetings—the American Medical Association, the American College of Surgeons and the American College of Physicians—had agreed to this procedure. On motion duly seconded and carried, the Committee on Postwar Medical Service concurred in this action.

Captain Eaton presented a comprehensive memorandum of the Bureau of Medicine and Surgery of the Navy, in which several new phases of the training of naval medical officers are outlined.

LICENSEURE

Dr. Walter L Biering, Secretary of the Federation of State Medical Boards, presented the following report, which was approved and publication authorized:

A questionnaire comprising five items was sent to the state board of medical examiners in each state, the District of Columbia and the territories of Alaska, Hawaii and Puerto Rico. The questions and responses thereto are submitted herewith. (There was no response from Hawaii, and Massachusetts deferred its reply.)

1 What will be the attitude of your board toward medical officers desiring to relocate after separation from military service, who are graduates of an approved medical school?

Practically all of the state boards express a willingness to cooperate with the returning medical officer in facilitating relocation but do not indicate any intent to accord credit for military service or to deviate from existing regulations of licensure by examination, reciprocity or interstate endorsement or by certification of the National Board of Medical Examiners. Three exceptions are noted.

New York: The State Department of Education has set up a special veterans' committee to pass on all applications of medical officers who are graduates of approved medical schools with a view to endorsing their previous licenses as far as possible.

Pennsylvania: The State Board of Medical Education and Licensure was instrumental during the recent general assembly in having an act passed whereby discretionary power is given the board to grant licenses to returning officers of the Medical Corps without examination. The board will adhere to the basic requirements under Pennsylvania law of a recognized medical school education and rotating internship. The act will remain in effect three years after the termination of hostilities. For those who are physically or mentally incapacitated during that period, the act will continue for five years after the cessation of hostilities.

North Dakota: Graduates of recognized schools who take a year's training in an acceptable hospital or college following dismissal from military service and present a satisfactory certificate from the Dean of said school will be granted a license without further examination.

2 What will be the attitude of your board toward those graduates of unapproved medical schools who have demonstrated their competence in connection with their military service. (It is limited that there are about 150 such officers.)

Apart from the several exceptions noted later, the state boards will not accept graduates of unapproved medical schools for licensure regardless of military service.

Arizona: Not recognized heretofore but will receive special consideration at next meeting of the board on October 6.

Georgia: The board requires graduates of unapproved medical schools to attend an approved school for one year and certification of the same by the dean.

Illinois: Admits to licensure graduates of an unapproved medical school located in that state but not otherwise.

Massachusetts: Same as Illinois.

New York: The Veterans' Committee will pass on all such applications and, if they can show one or two years of military service during which time they have been actively engaged in medical or surgical work, the board will endeavor to admit them to the licensing examination. If they have not had active medical or surgical work while in the armed forces one year of attendance at an approved medical school will be accepted.

3 Early in the war a number of medical officers entered military service without obtaining licensure in any state. What will be the attitude of your board in such cases?

The Vermont State Board of Medical Examiners responds to this question by stating that such applicants will be licensed without examination if in active service in the armed forces two or more years, provided they meet the other requirements for licensure. All of the other state boards will require the regular licensure examination.

The certificate of the National Board of Medical Examiners is accepted in all but four states (Florida, Texas, Montana and Wisconsin).

4 Does your state provide for temporary licenses? If so, what is the procedure?

The following states provide for some form of temporary licensure.

Maine: Issues temporary licenses for relocation during the war only and six months thereafter.

Nevada: Temporary licenses will probably be discontinued at the next meeting of the board in November 1945.

New Hampshire: Issues limited licenses in special forms of practice as in radiology.

New Jersey: Issues temporary licenses during the war or other emergency for not less than two weeks or not more than four months.

North Dakota: Temporary licenses issued only during the war emergency.

Pennsylvania: Statutory provision for temporary licenses for the duration of the war and six months thereafter.

Puerto Rico: Temporary licenses for the period of the war and six months thereafter.

Washington: Temporary licenses issued during the war emergency at the discretion of the Director of Licenses.

Kansas, Louisiana, Mississippi, South Dakota and Virginia: Temporary licenses are issued until the next meeting of the board.

5 Does your state require a license for hospital residents? If so, what is the procedure?

California, District of Columbia, Illinois, Indiana, Kansas, Louisiana, Michigan, Minnesota, Nevada, Ohio, Oklahoma, South Carolina and Wisconsin require a license from a hospital resident.

Nebraska and Texas require a license if the resident engages in independent practice.

Rhode Island requires a license after one year of residency.

New Jersey requires a license after two years of residency.

Puerto Rico requires a license for resident, but said license is granted without examination.

SUMMARY

1 Medical officers who are graduates of an approved medical school desiring to relocate after separation from military service will be required to satisfy the practice licensure regulations in the states where they desire to locate with the exception of the states of New York, North Dakota and Pennsylvania, where special consideration is given to this problem.

2 Medical officers who are graduates of unapproved medical schools will experience difficulty in obtaining licensure in any state except Illinois and Massachusetts. Arizona, Georgia and New York appear willing to give special consideration to such applications. In this connection two additional requirements were suggested: (a) complete statement of medical military service of each applicant and certification of the same or (b) one year of attendance in an approved medical school after separation from military service and certification of the same by the dean. These were submitted to the state boards without bringing forth any special reaction or comment. It would appear that the next step in this problem should be taken by the two educational agencies, the Association of American Medical Colleges and the Council on Medical Education and Hospitals of the American Medical Association.

3 Medical officers who entered military service without obtaining a license to practice in any state will evidently be required to take the regular licensure examination in the state concerned. Diplomates of the National Board of Medical Examiners will be exempt from these examinations wherever the certificate of the board is accepted. The Vermont board expresses also a liberal attitude toward such applicants.

4 Early in the war period there was a general expectation that provisions for temporary licensure would be established in most of the states but the opposition encountered by state licensing boards restricted the same to a limited number of states and then only for the duration of the war and six months thereafter.

5 In the states where a license is required for hospital residents a further inquiry will be necessary to ascertain the attitude of the respective state boards as to whether this requirement applies to medical officers carrying on their advanced training in hospitals approved for residences which might act as a barrier to such training. In the seventeen states and the District of Columbia having boards of examiners in the basic sciences certification by such boards is required before admission to medical licensure.

NEW BUSINESS

The Chairman and the Secretary were requested to prepare a report of the work of the Committee on Postwar Medical Service for presentation to the House of Delegates of the American Medical Association at its meeting to be held in Chicago December 3 to 6.

Colonel Bickel informed the Committee that he had received orders to close the Liaison Office of the Surgeon General of the Army that has been maintained at American Medical Association headquarters since October 1940. He expressed the appreciation of the Surgeon General for the splendid cooperation received, as well as his own sincere gratitude to all concerned who have been of assistance during the time he has been in charge as Liaison Officer. The Chairman thanked Colonel Bickel for his efforts and particularly for his excellent work in the conduct of the Bureau of Information.

Father Schwitalla presented a letter he had received from Dr. C. Willard Camalier, chairman of the War Service and Postwar Planning Committee of the American Dental Association, concerning surplus dental supplies that might be obtainable for the use of young dentists going into practice in needy areas. Action on Dr. Camalier's communication was postponed until the next meeting.

TIME AND PLACE OF NEXT MEETING

It was decided that the next meeting of the Committee would be held at American Medical Association headquarters, Saturday, Dec. 1, 1945.

The meeting adjourned at 1:15 p. m.

Washington Letter

(From a Special Correspondent)

Nov. 12, 1945.

Kelley Proposal on Artificial Limb Research Is Opposed

Champions of the Veterans Administration are none too pleased about the proposal of Representative Augustine B. Kelley, Democrat of Pennsylvania and chairman of the subcommittee on aid to the physically handicapped, that future government research on artificial limbs be centered in the U. S. Public Health Service instead of in the Veterans Administration. Major Gen. Paul R. Hawley, assistant administrator of veterans affairs in charge of medicine and surgery, has announced that the Veterans Administration would take over on January 1 all research now being done by the Army, Navy and National Research Council's prosthetic committee. Funds provided the Committee on Prosthetic Devices will run out at the end of the year, and the Veterans Administration plans to ask for an appropriation from Congress to continue research throughout the country and to carry on the \$500,000 in contracts with industrial laboratories now held by the committee.

Representative John E. Rankin, Democrat of Mississippi, chairman of the Veterans Committee, said that Mr. Kelley was mistaken in his opinion that the Board of Prosthetic and Sensory Devices, now a function of the Office of Scientific Research and Development, should be transferred to the Public Health Service instead of to the Veterans Agency. The Kelley committee has announced an eleven point program to guarantee proper provision of prosthetic devices for veterans, as follows: 1. That all skilled artificial limb workers be returned from military duty. 2. That the Veterans Administration provide limbs freely and from whatever source the veteran selects. 3. That procedure for securing limbs be simplified. 4. That the Federal Trade Commission police the artificial limb industry scrupulously. 5. That veterans be reimbursed for time lost because of unsatisfactory appliances. 6. That red tape of having the men in charge of the Veterans Administration cared for by the War and Navy departments be overcome by contract arrangement. 7. That the federal government's obligation to undertake research until substantial improvement in prosthetic devices be made clear. 8. That any improvements created at federal expense should be free of royalty. 9. That the Department of

Justice should continue investigating antitrust violations in limb making. 10. That the federal government research be placed in the U. S. Public Health Service. 11. That the Board for Prosthetic and Sensory Devices and its committee work should be transferred at once to the Public Health Service.

No comment was immediately forthcoming on the statement in Chicago by Dr. Paul E. Klopsteg, chairman of the Committee on Prosthetic Devices of the National Research Council, that artificial limbs now being supplied veterans have seven major faults.

Bernard Baruch Endorses National Science Foundation

Elder statesman Bernard M. Baruch, adviser to presidents since Woodrow Wilson, fully endorsed legislation for a national science foundation in his testimony before the Senate Military-Commerce subcommittees considering bills to create a federally financed program to aid research. He declared it to be a fact that Germans and Japanese will strive through science to create the means of waging another world war, and he suggested these courses for a peacetime United States scientific program: 1. Greatly increased scientific brain power, using scholarships and other aids to develop new scientific talent in American youth. 2. Continued military research in developing new weapons for national defense. 3. Intensified scientific war against disease. 4. Offsetting depletion of natural resources. 5. Stimulation of basic scientific research. 6. Dissemination of scientific information as widely as possible. 7. Creation of a new, permanent government agency to coordinate activities into an integrated, national scientific policy.

President Truman insists that any scientific discoveries coming from federally financed research be public property. He outlined this position in a letter written by Reconversion Director Snyder to Senators Kilgore, Democrat of West Virginia, and Magnuson, Democrat of Washington, who are holding the joint hearings on a national scientific foundation.

Approval of Mental Health Institute by Subcommittee

Unanimous approval was given by a House subcommittee headed by Representative J. Percy Priest, Democrat of Tennessee, to the bill to establish a \$4,500,000 mental health institute in the District of Columbia. In testimony before the joint House Interstate and Foreign Commerce subcommittee, Mr. Priest had reported that the name of the proposed institute was changed from the National Neuropsychiatric Institute to the National Institute of Mental Health. On the suggestion of the Budget Bureau several changes have been made in the bill. An amendment would put the fund for research into a common U. S. Public Health Service treasury, earmarking the money for institute use. This would prevent wide open federal aid to private institutions, because under the Public Health Service the fund cannot be used to subsidize private hospitals.

Coming Medical Meetings

American Medical Association House of Delegates, Chicago, Dec. 3-6. Dr. Olin West, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Allergy, Chicago, Dec. 10-11. Dr. Karl D. Figley, 316 Michigan St., Toledo 2, Ohio, Secretary.

American Association on Mental Deficiency, Cleveland, Nov. 28-Dec. 1. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American Society of Anesthetists, New York, Dec. 12-13. Dr. McKinnin L. Phelps, 745 Fifth Ave., New York 22, Secretary.

International College of Surgeons, U. S. Chapter, Washington, D. C., Dec. 7-8. Dr. Louis J. Garlepp, 16401 Grand River Avenue, Detroit, Secretary.

North Pacific Pediatric Society, Portland, Ore., Dec. 1. Dr. Aldis B. Johnson, Cobb Bldg., Seattle 1, Washington, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Nov. 26-29. Dr. Elmer R. Musick, 512 Medical Arts Bldg., Oklahoma City, Secretary.

Puerto Rico, Medical Association of, San Juan, Dec. 14-16. Dr. Rafael A. Vilar, P. O. Box 3866, Santurce, Secretary.

Southern Surgical Association, Hot Springs, Va., Dec. 4-6. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Medical Legislation

MEDICAL BILLS IN CONGRESS

Amendment of G. I. Bill of Rights

The Senate has passed H. R. 3749, with amendments, a bill to amend the G. I. Bill of Rights. As passed by the Senate, this bill, among other things, (1) eliminates the requirement in the existing law that veterans must show that education was interrupted by service in order to qualify for the educational benefits of the law, extends the time from two to four years within which a course must be initiated and extends the time within which education or training may be afforded from seven to nine years; (2) adds a provision for short, intensive courses under contract with approved institutions, with authority to pay more than the pro rata customary charges; (3) increases the subsistence allowances under the title relating to education from \$50 to \$65 a month in the case of veterans without dependents and from \$75 to \$90 a month in the case of veterans with dependents; (4) provides that any person while on terminal leave, or while hospitalized pending final discharge, may be afforded the benefits of the law relating to education and loans, and (5) extends the time within which veterans may apply for the guaranty of a loan to ten years after the termination of the war.

Social Security Act Amendments

A bill, H. R. 4551, introduced by Representative Jackson, Washington, proposes to amend the Social Security Act to provide for a National Social Insurance System under which would be made available to covered persons retirement, survivors and extended disability insurance benefits. Among other things, the Social Security Board, after consultation with the Surgeon General of the United States Public Health Service and the Office of Vocational Rehabilitation, would be authorized to make provision for furnishing medical, surgical, institutional, rehabilitation or other services to disabled individuals entitled to receive the extended disability benefits if such services may aid in enabling such individuals to return to gainful work.

National Mental Health Act

Representative Priest, Tennessee, has introduced H. R. 4512, to amend the Public Health Service Act to provide for research relating to psychiatric disorders and to aid in the development of more effective methods of prevention, diagnosis and treatment of such disorders.

Miscellaneous

Two new bills propose methods of prevention of stream pollution. S. 1462, introduced by Senator Barkley, Kentucky, provides for water pollution control activities in the United States Public Health Service and for federal aid in the form of grants-in-aid, loans or both to any state, municipality or other public body for the construction of necessary treatment works to prevent the discharge of untreated or inadequately treated sewage "into the surface or underground waters in or adjacent to any state." The other bill, S. 1536, introduced by Senator Kilgore, West Virginia, proposes to encourage the prevention of stream pollution by allowing amounts paid for plants for the treatment of industrial waste as a deduction in computing net income.

Two other bills have been introduced relating to the discharge of members of the armed forces who desire to resume their education or training. One bill, H. R. 4376, introduced by Representative Schwabe, Oklahoma, provides that there shall be released from active duty for the period of one year any member of the military or naval forces who applies for such release and submits with his application an affidavit of his intention to resume his education or training by enrolling in an educational or training institution. If at the end of that year the member submits satisfactory evidence that he has made passing grades in the institution which he has attended, he will be granted a certificate of honorable discharge. The other bill, H. R. 4511, introduced by Representative Gillie, Indiana, likewise provides for the discharge from the armed forces of any person who desires to resume his education or training, if his

education or training was impeded, delayed, interrupted or interfered with by reason of his entrance into the service. If any such person was not over 25 years of age at the time he entered the service he will be deemed to have had his education or training impeded, delayed, interrupted or interfered with. This bill, too, provides for the discharge of any person who desires to return to his business or profession which he was forced to discontinue or place in other hands at the time of his induction or enlistment into the military service.

Official Notes

NBC NETWORK BROADCASTS TO BE RESUMED

Beginning Saturday December 15 at 4 p. m. Eastern Standard Time (3 p. m. Central Standard Time, 2 p. m. Mountain Standard Time, 1 p. m. Pacific Standard Time) the American Medical Association will resume its nationwide dramatized radio health programs on the network of the National Broadcasting Company and associated stations. The broadcasts will run for twenty-six weeks.

The title for the network broadcasts will be "Doctors at Home," which will represent the sixth consecutive year of broadcasting under the general title "Doctors at Work," which was modified during the war years to "Doctors at War" and "Doctors Look Ahead." "Doctors at Home" will deal, as its title indicates, with the return of doctors from the war and their reabsorption and readjustment into life at home. Going back to the "Doctors at Work" formula, the programs will be in story form, continuous from week to week. The fictitious doctor who was the hero of "Doctors at Work" (Dr. Tom Riggs, who was several times mistaken for a real doctor instead of a radio character) will return from his military service and will resume his practice in a typical American town. Listeners will meet again Dr. Riggs's wife Alice and child, the rest of the Riggs family and their friends, and the doctors and citizens of the community among whom Tom finds his place as a rising young physician and a progressive citizen.

The fictitious story of Dr. Riggs will be used as a vehicle for dealing with modern medical advances such as new developments in drugs, advances in surgery, anesthesia, obstetrics and other branches of medicine. There will be a constructive attack on the problem of scarcity of physicians. How to choose a doctor, what to do until the doctor comes and other practical phases in health education will be part of the program.

Announcements will be carried in the radio columns of local newspapers. Locally, broadcasts may not be at the same time as the network broadcast, since many radio stations having a conflict between network programs and local time make a recording of the network program and broadcast it later in the day or even the next day.

APPOINTMENTS TO AMERICAN MEDICAL ASSOCIATION

Dr. William W. Bolton, who recently returned to the United States after service with the medical departments of the Ninth, Seventh and Third armies, has been appointed Assistant Director of the Bureau of Health Education. A graduate of Jefferson Medical College, Philadelphia, class of 1930, Dr. Bolton served with the Pennsylvania State Department of Health from 1935 to 1938, first as assistant director and later as director of the bureau of venereal disease control. Before entering the Army of the United States, he was on the staff of Yearbook Publishers, Chicago. Mr. George W. Cooley, since 1938 executive secretary of the Academy of Medicine of Toledo and Lucas County, has been named assistant to Mr. Thomas Hendricks, Secretary of the Council on Medical Service and Public Relations of the American Medical Association. Mr. Cooley will work on prepayment medical care plans. Mr. Cooley has served with the National Municipal League and the Cincinnati Regional Crime Commission. He is a graduate of the University of Cincinnati Post-Graduate School of Public Administration.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Personal.—Dr. Thomas Malcolm Blake has been named health officer of Winston County to succeed Dr. Hugh C. McRee, Hamilton, who resigned September 1. Dr. Marvin S. White, Hamilton, has been named to a similar position in Marion County also to succeed Dr. McRee.—Major Walter G. Haynes, M. C., has been appointed associate professor of neurosurgery and chief of the department at the Medical School of Alabama, Birmingham, effective November 1, newspapers report.

CALIFORNIA

Health Lecture Series.—The fall public relations program of the Los Angeles County Medical Association opened October 12 with a series of public health talks. The first session was devoted to "Penicillin—The Life Saving Miracle." The meeting October 19 was devoted to "The Truth About Venereal Diseases," October 26 "Preventive Medicine," November 2 "Modern Surgery" and "First Hundred Years of Anesthesia" and November 9 "Gifts of Modern Medicine." On November 16 "Blessed Events" was discussed.

Changes in Health Personnel.—Dr. Carl A. Scherer, Duluth, Minn., has been appointed health officer of the Sutter-Yuba Bi-County Health Unit, effective September 5. Before coming to California Dr. Scherer was for ten years health officer of St. Louis County, Minn., and director of Rural Health Unit 4 of the Minnesota State Board of Health.—Dr. Georgia N. Krusch, who has for the past year been head of the maternity and child care division of the Kern County Public Health Department, has been named director of a similar department for the King County (Wash.) Public Health Department.

ILLINOIS

Personal.—Robert D. Coghill, Ph.D., Peoria, has been appointed associate research director of Abbott Laboratories, effective November 1. Since 1939 he has been chief of the Fermentation Division, Northern Regional Research Laboratory, U. S. Department of Agriculture, in Peoria.

Chicago

Personal.—Mr. Ray E. Brown, formerly superintendent of the North Carolina Baptist Hospital, Winston-Salem, N. C., has been appointed assistant superintendent of the University of Chicago Clinics. He will be assistant to Dr. George Otis Whitecotton, superintendent.

Dudley Reed Retires.—Dr. Dudley B. Reed has retired at the University of Chicago School of Medicine with the title of professor emeritus of hygiene, department of medicine. Dr. Reed, who is health director of the university's student health service, retires under the age limit after thirty-four years service.

Course in Electrocardiographic Interpretation.—A course in electrocardiographic interpretation for graduate physicians will be given at Michael Reese Hospital by Dr. Louis N. Katz, Chicago, director of cardiovascular research. The class will meet each week starting Wednesday, February 13, for twelve weeks, from 7 to 9 p. m. Further information and a copy of the program may be obtained on application to the Cardiovascular Department, Michael Reese Hospital.

Class Endowment Fund Established.—A permanent endowment fund has been set up at the University of Chicago School of Medicine in the name of the class of 1944. The fund resulted from the proceeds from the sale of the first yearbook of the medical school, which was the activity of the class of 1944. According to the *Medical Alumni Bulletin* this establishes a precedent which, it is hoped, will inspire other classes to aid in placing the Medical Alumni Association on a permanently secure financial basis.

The D. J. Davis Lecture.—Dr. Carl E. Black, Jacksonville, Ill., will deliver the third annual D. J. Davis Lecture on Medical History at the University of Illinois College of Medicine, November 21. His subject will be "Medical Practice Before the Hard Roads." The Davis lecture series was established by the associates and friends of Dr. David J. Davis on his retirement

as dean of the college of medicine in 1943. Dr. Black is known for his collection of photographs of physicians, which has been given to the Illinois State Medical Society and which is being augmented through the work of Joseph Merante Jr., portrait photographer of New York (*THE JOURNAL*, March 3, p. 536).

MICHIGAN

Ninety-Four Years of Age.—Dr. Homer P. Mix, formerly of Riverside, observed his ninety-fourth birthday October 10 at the home of his daughter in Benton Harbor. Dr. Mix graduated at the Hahnemann Medical College and Hospital, Chicago, in 1880.

Harley Haynes Leaves University Hospital.—Dr. Harley A. Haynes has retired as director of the University Hospital, Ann Arbor, after serving in the position for twenty years. He has reached the automatic retirement age of the University of Michigan Medical School, Ann Arbor. Dr. Albert C. Kerlikowske, Ann Arbor, who graduated at the University of Michigan Medical School in 1923 and served his internship at the hospital, has been named director of the hospital to succeed Dr. Haynes.

New Tuberculosis Law.—On September 6 a new law covering the care of tuberculous patients in Michigan became effective. In this law, for the first time, treatment of tuberculosis is described as protection of public health, and the state or local health officer is empowered to arrange for treatment and care of persons who have the disease. This responsibility was formerly the duty of relief or welfare agencies, and the treatment of tuberculosis was considered a form of relief instead of a public health matter. One important change which will be brought about by the new law is that patients with tuberculosis no longer will be required to mortgage their securities to pay for hospital care or to make reimbursement.

Members of New Health Commission.—Dr. Charles F. Wagg, executive secretary of the former State Hospital Commission, has been named acting executive officer of the new Michigan Department of Mental Health, pending formulation and adoption of a permanent organizational structure. The new department, which was set up by the 1945 legislature, is now attempting to find a satisfactory candidate for the position of director of mental health. Members of the health commission created within the newly established department of mental health consist of the following: William J. Norton, Detroit, chairman, Mrs. Carl C. Blankenburg, Kalamazoo, Edward A. Bilitzke, West Branch, Dr. Raymond W. Waggoner, Ann Arbor, and Dr. Harry B. Zemmer, Lapeer. All activities of the State Hospital Commission are transferred to the new department of mental health, while the health commission shall be a body corporate within the department.

MONTANA

Dr. Cogswell Retires.—Dr. William F. Cogswell, Helena, executive secretary of the Montana State Board of Health, has announced his retirement, effective April 1, 1946. Dr. Cogswell joined the state board as secretary in 1912, coming from Livingston, where he had been health officer for Park County. According to *Montana Health*, Dr. Cogswell had planned to retire September 1 but extended the date to the expiration of his present appointment to give him additional time to complete a history of research on control of Rocky Mountain spotted fever. Dr. Cogswell graduated at Dalhousie University Faculty of Medicine, Halifax, in 1894. At a recent meeting of the board of health, Dr. David T. Berg, Helena, was named president, succeeding Dr. Roy V. Morledge, Billings, who becomes a member of the board. Dr. Richard C. Monahan, Butte, was named vice president.

NEW YORK

State Society Seeks Help in Compensation Expense.—The house of delegates of the Medical Society of the State of New York recently adopted a resolution pledging the society to take affirmative action toward having the state of New York assume a part of the financial expense, now borne entirely by county medical societies in New York, of administering the medical provisions of the workmen's compensation law. Dr. Joseph C. O'Gorman, Buffalo, in offering the resolution, pointed out that while the workmen's compensation law holds the county medical societies throughout the state responsible for licensing and supervising all compensation medical bureaus, it makes no provision for supplying the necessary funds to carry on the work. The action of the house of delegates paved the way for obtaining the required monies. The resolution expressed the view that all expenses incurred by

the county medical societies in this connection are costs properly chargeable to the administration of the entire workmen's compensation law. The resolution has application to fifty-seven of the sixty-one county medical societies throughout the state, the four in the Greater New York area being excluded, since the work referred to in the resolution is there performed by the state medical practice committee at the expense of the state.

Endowment Fund for Neuropsychiatry.—An endowment fund of \$2,153,954 has been established for a neuropsychiatric clinic at the University of Rochester School of Medicine and Dentistry, it was announced October 30. The fund is in addition to the building fund for the new structure, the cost of which is tentatively estimated at about \$600,000. Construction of the clinic is expected to start early in 1946 and it is hoped that the building will be completed within a year. The new structure will face Crittenden Boulevard adjacent to Strong Memorial Hospital and will be joined to the hospital by a corridor. It will be five stories high with a solarium on top and will contain physical and occupational therapy and recreational facilities for patients and ample laboratory space for active research and investigation. A committee of the medical school faculty has been surveying the field throughout the country to select a professor of psychiatry to head the clinic and help prepare plans for the facilities and staff organization. The clinic will be operated as a unit of the medical school and coordinated with the university's Strong Memorial and Municipal hospitals, the teaching hospitals of the school. It is contemplated that it will be used for the study and care of persons having functional nervous disorders rather than for those with extreme mental ailments. Provision will be made for beds for about 70 inpatients, and extensive use of the clinic for ambulatory patients is planned. Funds for the project were given by Mrs. Helen W. Rivas of LeRoy.

New York City

Course in Industrial Medicine.—The Long Island College of Medicine, Brooklyn, will conduct its fourth postgraduate course in industrial medicine January 14-February 1 under the auspices of the department of preventive medicine and community health. Instruction in the course will be intensive and practical and emphasis will be placed on health problems of workers under peacetime conditions. Morning, afternoon and evening sessions will be held each day during the three week period and lectures and seminars at the college will be supplemented by clinics and demonstrations in medical departments of cooperating industries, in various teaching hospitals and in governmental or other agencies active in the field. During the first week the program will be devoted to medical administration in industry, in the second week to internal medicine in industry and the occupational diseases and in the final week to industrial surgery. Provision will also be made for a limited number of those enrolled in the course to obtain subsequent additional supervised in-plant training in well established industrial medical departments. Additional information may be obtained from Dr. Thomas D. Dublin, professor of preventive medicine and community health at the medical school, 248 Baltic Street, Brooklyn.

"Model Unit" Set Up for Infantile Paralysis.—What is said to be a "model unit" for teaching and research has been started at Knickerbocker Hospital. The teaching and research aspects of the new service will be financed by a grant of \$100,000 from the National Foundation for Infantile Paralysis, while \$425,000 from the foundation's Greater New York chapter will pay for supply, equipment and treatment of patients. The new center is not intended to provide care for all paralysis sufferers in the city but will serve as a training center for professional personnel. When in full operation it will draw physicians from all over the country interested in treating the disease. It will give them the opportunity to study care of the disease under ideal conditions, to study the latest types of treatment. At present there are 19 patients, but 35 can be accommodated. The new unit is expected to make it possible to treat infantile paralysis cases in one hospital from the onset of the disease until final disposition instead of having patients attend several institutions at various stages of the disease for different treatment. Dr. Philip M. Stimson, associate professor of clinical pediatrics at Cornell University Medical College, New York, will direct the new service. He will be assisted by Dr. Dorothy B. Jackson, resident physician at Knickerbocker Hospital. In addition, the staff will include two physicians, five physical therapists, one occupational therapist, eighteen nurses, an executive secretary and several persons trained in the application of "hot packs." The new unit

will occupy the entire fifth floor of the hospital. Phases of treatment will include pediatric care, physical therapy, rehabilitation and occupational therapy, and orthopedic support and reconstruction.

OREGON

State Medical Election.—Dr. Stanley Lamb, Portland, was named president-elect of the Oregon State Medical Society at a meeting of the house of delegates in Portland September 1-2. Dr. Lansford M. Spalding, Astoria, is president. Other officers include Drs. James C. Hayes, Medford, Burton A. Myers, Salem, Raymond M. McKeown, Coos Bay, vice presidents; Thomas S. Saunders Jr., Portland, secretary, and Cecil J. Ross, Portland, treasurer. Dr. Frank R. Mount, Portland, is delegate to the American Medical Association, with Dr. Edward H. McLean, Oregon City, as alternate.

PENNSYLVANIA

State Medical Election.—Dr. Howard K. Petry, Harrisburg, was named president-elect of the Medical Society of the State of Pennsylvania at the annual meeting in Philadelphia October 23-24. Dr. William L. Estes Jr., Bethlehem, was installed as president. The society voted to increase its dues from \$10 to \$20, attributing the need to the fact that for the past four years it did not receive annual dues from an average of two thousand members engaged in military service.

Philadelphia

Isaac Starr Named Dean at Pennsylvania.—Dr. Isaac Starr, Milton Bixler Hartzell research professor of therapeutics, University of Pennsylvania School of Medicine, has been elected dean of the medical school, effective November 6. As dean, he succeeds Dr. William Pepper who is retiring with the title of dean emeritus. Dr. Pepper became a member of the medical faculty at Pennsylvania in 1899 and has served as dean for thirty-three years. Dr. Starr graduated at the medical school in 1920. He joined the teaching faculty in 1922 as instructor in the department of pharmacology, subsequently serving as assistant professor of clinical pharmacology and associate in medicine. He became Hartzell professor in 1933, being the first to hold this position, which was established through the will of the late Dr. Milton B. Hartzell, who also had been a member of the faculty. With his election as dean, he resigned from the Hartzell professorship and has been appointed professor of therapeutics.

SOUTH CAROLINA

State Medical Election.—Dr. James C. McLeod, Florence, was chosen president-elect of the South Carolina Medical Association at its house of delegates meeting in Columbia, October 3. Dr. William T. Brockman, Greenville, is president. Other officers include Drs. Enoch M. Dibble, Marion, vice president, and Dr. Julian P. Price, Florence, secretary-treasurer. Dr. Hugh Thomas A. Pitts, Columbia, is delegate to the American Medical Association. Actions taken at the meeting included the increase of the annual dues of the association from \$10 to \$20 to help raise more funds for the society's ten point program. (THE JOURNAL, June 17, 1944, p. 1505) and agreement to employ a public relations officer to act as "director of public relations and counsel" for the state association.

VERMONT

Conference on Social Welfare.—A symposium on public problems was a feature of the twenty-ninth annual conference of social welfare in Burlington, October 25-26. The theme of the meeting was Approaches to Social Security in Vermont. Dr. Frederick C. Thorne, director, Brandon State School, presided, and the following spoke:

Dr. Erval R. Coffey, Washington, D. C., medical director, U. S. Public Health Service.

Mr. W. Arthur Simpson, formerly director, Old Age Assistance Department.

Dr. Harold B. Pierce, professor of physiologic chemistry, University of Vermont College of Medicine, Burlington.

Dr. Charles F. Dalton, Burlington, executive secretary, state department of public health.

The Vermont Society for Mental Hygiene met next day, October 27, at the Fleming Museum, University of Vermont, Burlington, for the following program:

Rev. James L. Hall, Burlington, Don Bosco School.

Mr. Earle Wingate, Burlington, Training Opportunities Offered by Veterans Administration.

Mr. Francis S. Irons and Mr. Donald M. Eldred, Burlington, of the state department of education, Some Psychologic Aspects of Civilian Vocational Rehabilitation.

A member of the Alcoholic Foundation, New York, Alcoholics Anonymous.

Dr. Robert V. Seliger, Baltimore. The Psychiatrist Looks at the Alcoholic Patient.

VIRGINIA

Course on General Medicine.—The department of medicine of the University of Virginia in conjunction with the Medical College of Virginia, Richmond, is planning to offer an intensive two week refresher course in general medicine every three months for the next year. These courses will comprise lectures, clinics, ward rounds, clinicopathologic conferences and round table discussions. The first course will be held December 3-15 at the University of Virginia, and any physician wishing further details should address Box 1725, University Station, Charlottesville, Va. Those desiring information about courses to be given by the Medical College of Virginia in March and September should address Dr. Jacques P. Gray, dean, Medical College of Virginia, Richmond.

GENERAL

New Journal on Blood.—In January the first issue of *Blood*—The Journal of Hematology will make its appearance. Dr. William Dameshek, Boston, is editor-in-chief, with Drs. Charles A. Doan, Columbus, Ohio, Thomas Hale Ham, A. U. S., Edgewood Arsenal, Md., Roy R. Kracke, Birmingham, Ala., Nathan Rosenthal, New York, and Maxwell M. Wintrobe, Salt Lake City, as associate editors. Dr. George R. Minot, Boston, is consulting editor. An advisory editorial board has been named from among ranking specialists to represent all aspects of hematologic work. International interest is assured through a board of foreign contributing editors. Editorial offices are at 25 Bennet Street, Boston, and business affairs will be in the hands of Grune and Stratton, 381 Fourth Avenue, New York, who will publish the journal. The Waverly Press, Baltimore, is the printer. The journal will be published bimonthly.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended November 3 have been received from the division of public health methods, U. S. Public Health Service, as follows:

Award in Enzyme Chemistry.—The Paul-Lewis Laboratories Inc. of Milwaukee has established an annual award for highly important work in the field of enzymes and requested the American Chemical Society to administer the award in a manner similar to other awards administered by the society. At the recent board of directors meeting the proposal was accepted by the society. The award is to be made for the purpose of stimulating fundamental research in enzyme chemistry in the United States by young men educated in a college or university in the United States. The award is to consist of \$1,000 and a bronze medal (or diploma). An additional amount up to \$150 or as much thereof as necessary is available to the recipient toward traveling expenses to the national meeting of the American Chemical Society, at which the award will be presented. To be eligible, a nominee shall be a citizen of the United States and a graduate of a United States college or university, shall not have passed his thirty-sixth birthday on April 30 of the year of the award and shall have accomplished noteworthy research in enzyme chemistry. For the purpose of this award the presence of an enzyme

action must be unequivocally demonstrated in the nominee's work. Nominations for this award, as well as members of the award committee, are limited to noncommercial chemists. John J. Willaman, Ph.D., of the Eastern Regional Research Laboratory of the U. S. Department of Agriculture has been appointed chairman of the canvassing committee.

Government Services

Penicillin Distribution Unit No Longer Operating

All communications regarding penicillin should be addressed to the Chemicals Division, Civilian Production Administration, Washington 25, D. C. The Civilian Penicillin Distribution Unit, formerly accepting these communications, was closed in April 1945. Information has been received indicating that inquiries are still being addressed to the Distribution Unit, which is no longer operating.

New Director of Neuropsychiatric Services

Dr. Daniel Blain, New York, has been appointed director of neuropsychiatric services in the Veterans Administration. Dr. Blain, who is a commissioned officer in the U. S. Public Health Service Reserve, has been serving as psychiatrist with the War Shipping Administration. Commander Blain will direct the care of mental patients and also will supervise the establishment of additional mental hygiene clinics.

Richard Plunkett Named Field Consultant of Health and Sanitation

Dr. Richard J. Plunkett, Major, M. C., A. U. S., has been appointed field consultant for the division on health and sanitation, Institute of Inter-American Affairs. The appointment is part of the institute's plan to mold wartime cooperative advances in hemisphere health into permanent peacetime channels. Major Plunkett has already started a lengthy inspection and consulting tour which will take him to Bolivia, Chile, Uruguay, Peru, Ecuador, Colombia and the republics of Central America, according to an announcement.

Members Named to Surplus Property Unit

Hazen Dick, N. F. MacDonald and Carl E. Schwob, M.S., have been appointed by the U. S. Public Health Service to the staff of its surplus property unit. The unit, which is under the supervision of Dr. Joseph O. Dean, San Juan, Puerto Rico, senior surgeon, will assist the surplus property board in administering section 13 of the surplus property act, which gives special consideration to the needs of tax supported and tax exempt organizations for surplus property suitable for health protection use. Mr. Dick, who has been secretary of the council on administrative practice of the American Hospital Association, will serve as chief of the medical supply section. Mr. Schwob will be chief of the engineering section and Mr. MacDonald has been detailed to the hospital and medical fields in the office of surplus property.

Need for Pharmacists

There is a need for pharmacists in Veterans Administration and U. S. Public Health Service hospitals and dispensaries throughout the country. The entrance salaries are \$2,320 and \$2,980 per annum. Additional compensation is given for all authorized time worked over forty hours a week. Appointments to federal positions which are subject to the civil service rules and war service regulations are made through the U. S. Civil Service Commission. No fee is charged. Application may be made to the U. S. Civil Service Commission, Washington 25, D. C. Pharmacists who obtain an entrance salary of \$2,320 (P-1) act as pharmacist or assist the pharmacist in charge at a hospital or dispensary, compound doctors' prescriptions or other medicines, manufacture U. S. P. and N. F. preparations, keep narcotic records, maintain stocks and supplies and perform related work as required. A pharmacist who enters at \$2,980 (P-2) is in charge of a pharmacy in a hospital. Positions as narcotic agents (\$2,980 a year) may also be filled from the P-2 list of eligibles.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Oct. 13, 1945.

Improved Medical Services in Industry

Important recommendations for the training of medical officers, nurses and others concerned with the problem of health in industry are made in a report of the Education Committee of the Association of Industrial Medical Officers. The present facilities for the training of medical students are described as extremely scanty in London and not much better in the provinces. The report suggests that in the future all medical students should be trained to recognize that the daily occupation of a patient, the economic effect of illness and the necessity for restoring earning capacity are all important aspects of everyday practice. Students should also receive special training in accident surgery, attend lectures on occupational medicine and spend at least three days in a factory where they can learn about the normal work of the industrial medical officer. All teaching hospitals should have on the staff or available to them an industrial medical officer to give undergraduate instruction.

For postgraduates who intend to devote themselves especially to industrial medicine, a broad basic training in general medicine followed by special training of three types is recommended. These types are adapted respectively to the needs of the consultant and specialist in industrial medicine, the whole time industrial medical officer and the man who takes one of certain medical appointments, such as examining surgeon, or becomes a factory medical inspector. The committee also recommends the institution of a diploma in industrial health to be given by one of the royal medical colleges.

The training of nonmedical personnel is also recommended. Nurses should receive instruction, whole time or part time, to fit them for the important part they play in any industrial health plan. The social worker should have a wider training in industrial subjects, since she is the most important link between the hospital and industry. General education in health matters is also advocated for the staff and workers in industry—for the works manager, technicians, foremen, the workers themselves and especially the personnel manager, so that all can play an intelligent part in preventing accidents and disease.

The committee also recommends further academic appointments in industrial medicine. Already university posts of a higher type are being instituted at Manchester, Durham and Glasgow, which are great industrial centers. It is suggested that further appointments should be made at London, Birmingham and Liverpool universities.

A licensing body, the Society of Apothecaries of London, has instituted a diploma in industrial health. It will be open to physicians who have been engaged in whole time practice of industrial medicine for not less than two years, or in part time practice for not less than four years. The society understands that courses in the subject are to be held in the future. Subject to their fulfilling the society's regulations, they will be recognized as qualifying for admission to the examination.

Nazis' Last Plans for Poisoning the Invaders

A secret Nazi paper has been published by the United Nations War Crimes Commission. It reveals that a meeting of German chemical experts was held to discuss the means of poisoning the Allied invasion forces and of providing suicide tablets for the Germans themselves. These tablets were presumably used by Himmler and lesser Nazis. The paper is a report of the proceedings of a conference held under high auspices at an SS police institution in Berlin on Oct. 16, 1944.

Mobile Exhibition of Wartime Advances in Medicine

St. Mary's Hospital, where penicillin was discovered, has adopted a novel method of appealing to the public for funds required for rebuilding. This is an exhibition train of some of the wartime advances in medicine, which, starting from the Paddington terminus of the Great Western Railway, is touring the country. The coaches concerned were formally handed over to the chairman of the railway by Sir Almroth Wright, principal of the Institute of Pathology and Research of St. Mary's Hospital. Every stage in the production of penicillin is shown. DDT is exhibited not only as a destroyer of mosquitoes but as an ally to the housewife in eliminating insect pests. There is a section devoted to vitamins, with a useful guide to the choice of a balanced diet. In the section on vaccines the visitor learns in a simplified way how Sir Almroth Wright protected modern armies against typhoid. The wonders of the electrocardiograph also are shown.

PARIS

Oct. 6, 1945.

New Code of the Medical Profession

Before the war the Medical Professional Organizations (Syndicat des médecins) protected the professional interests and also dealt with matters of discipline and ethics. In 1936, in order to achieve the latter aim, the necessity for creating a special organization, the Order of Physicians, was discussed; war prevented its realization. The Vichy government dissolved the professional associations and created the "Order of Physicians," which dealt with functions pertaining to the profession of doctor. But the order created by Vichy was an autocratic organization, which accepted the German law, excluded Jewish doctors and sent doctors to Germany. It was constantly in conflict with the Academy of Medicine, which courageously defended the independence and the dignity of the French medical corps. Letters which your correspondent addressed to THE JOURNAL reporting this fact did not arrive because of the war.

After the liberation, the Medical Professional Organizations were reestablished by the order of the minister of public health on Dec. 15, 1944. Their activity is restricted to the professional defense of members of the organizations. In agreement with the representatives of the medical profession, the minister of public health promulgated a new code, which appeared on Sept. 28, 1945 in the *Journal officiel*. The Order of Physicians makes membership compulsory for all doctors practicing in France and in Algeria. Membership in the order entitles the physician to practice anywhere in the national territory. The Order attempts to maintain principles of morality, probity and devotion on the part of the doctor and safeguards the independence of the profession. The basic organization is the district board, which is elected for six years by doctors who must be at least 30 years old. The deliberations of the district board are not public. It does not have to take into account the political or religious opinions or attitude of the members of the Order. The regional board consists of eight members delegated by the district boards. The regional board, which alone has a disciplinary power, can inflict the following disciplinary penalties: warning, rebuke, temporary or permanent prohibition of the power of exercising medical functions in establishments of the state and of townships, temporary interdiction (up to three years) of practicing and, finally, removal of a doctor's name from the list of the Order. The doctor appearing before the board can obtain assistance either of a fellow doctor or of a barrister. After three years, expelled doctors may be reinstated in their profession.

The national board of the Order, composed of twenty-four members, is elected by the district boards for a period of six

years; to those members is added one member of the Academy of Medicine. The national board of the Order is the most important counselor of the minister of public health. It directs the work of the district boards. Its disciplinary section hears the appeals against the decisions of regional boards. A final appeal must be made to the "Conseil d'état," the highest court in the land. The Order is authorized to promote mutual help and retirement benefit organizations for the members. Similar Orders have been created for the professions of surgeon, dentist and midwife.

Hookworm Therapy of Polycythemia Vera

In a clinical lecture at the Saint Antoine Hospital, Brumpt described 8 cases of polycythemia vera treated with provoked ancylostomiasis, which was employed for the first time by Duvoir and Brumpt in 1939. The patient is infected through the skin with 400 to 700 larvae, according to his weight and the degree of polyglobulia. This infection causes gastric pains and transient diarrhea, which can be treated with opium. These painful discomforts are largely compensated for by the favorable results of the treatment. By the end of the first month the erythrocyte count has been progressively lower, reaches 4,000,000 at the end of the third month and has become normal at about the end of the sixth month. The number of leukocytes reaches a maximum of 40,000 to 60,000 the third month and then diminishes. The eosinophils comprise 75 per cent in the third month, 20 per cent in the sixth and 15 per cent after one year. A clinical amelioration becomes apparent: somnolence, headache, vertigo disappear, the blood pressure is lowered, albuminuria disappears and the urea in the blood becomes almost normal. This amelioration persists for months and years. Ancylostomotherapy is an ambulatory method, which does not in the least interrupt the patient's occupation. The action of Ancylostoma is protracted. It can, if necessary, be interrupted by administration of anthelmintics. Ancylostomotherapy is indicated in all the stages of polycythemia vera and perhaps even in certain cases of secondary polycythemia. Brumpt recommends especially this method in cases of hypertension, cardiac and renal disease and the treatment of aged patients when phenylhydrazine therapy is contraindicated; it can be associated with other treatments. Artificial ancylostomiasis is contraindicated in splenic tuberculosis with polycythemia. The author concludes that the temperature of France is not favorable to the propagation of Ancylostoma. On the other hand, Ancylostoma does not multiply in the infected patient. Notwithstanding, the treatment is not to be employed with miners, men working in a huge tunnel or patients who are likely to leave France for tropical countries.

Professor Fleming in Paris

At the invitation of the minister of public health, F. Billoux, Professor Fleming paid a visit to the Paris medical institutions. On the 4th of September he was received by the Académie de médecine in a formal meeting. G. Brouardel, president of the academy, H. Vincent and Léon Binet gave addresses. Professor Fleming replied by indicating two significant elements in his career as a scientist. First of all was chance, but, as Pasteur said, "chance favors intelligences that are ready." Secondly he emphasized that, in his opinion, the method of scientific research must be that of an isolated scientist who is able to follow the lead of an observation up to discovery. Then comes the team of scientists, without which his discovery could not have been realized and penicillin, as we use it today, developed.

Professor Fleming also visited the Pasteur Institute and the center for the production of penicillin in Paris, created on the initiative of the minister of public health and the army

medical corps. He was received by General de Gaulle, chief of the provisional government, and was awarded the gold medal of the medical service and nominated Commander of the Order of Public Health.

BELGIUM

(From a Special Correspondent)

Oct. 20, 1945.

Medical Days in Brussels

In order to revive the traditional institution of the Medical Days of Brussels, which were interrupted by the war, and to prove that Belgian hospitality remains unchanged, the organizers of this meeting took the initiative of calling together a veritable medical congress. The program included a surgical morning clinic at the University Hospital and in other surgical institutions. In the afternoon there were four important conferences.

Professor E. Renaux, who directed the Belgian transfusion service during the war period demonstrated the advantages and disadvantages of blood, plasma and serum transfusions.

Professor R. Danis, with the aid of films made for the English audience, gave his conference in English on axial pressure and bone growth.

Professor André Simonart of the faculty of Louvain, recently returned from Buchenwald, described the treatment of the repatriated who suffered from malnutrition, illustrating his lecture with a film on the results of vitamin therapy.

Dr. Gustave Coryn, president of the Belgian Society of Surgery, presented results of his experience in the treatment of pulmonary abscess.

International Committee on Military Medicine

The international Committee on Military Medicine and Pharmacology met for the first time since the war in a special session in Brussels on January 29 and 30. In view of the circumstances the number of nations represented was small and comprised only the delegates from the United States, France, Great Britain, Switzerland and Belgium.

The presidency, previously held by General Reynolds, at present in Chicago, was transferred to Col. Robert B. Hill, who was informed to this effect by a telegraphic message.

It was decided to continue the publication of the *Bulletin International des Services de Santé des Armées* with the cooperation of the national correspondents of the International Office of Military Medicine and to resume all the activities of this office.

The next congress is to be held at Bern; the date will be fixed later by the Swiss government.

The committee has further decided to cooperate with the interallied surgical conference planned and organized in Paris by the administration of the health service of the French war ministry.

Marriages

PETER W. CHERNENKOFF, Bend, Ore., to Lieut. Ruby A. Brenden in St. Valery, France, June 27.

DOUGLAS JENNINGS JR., Bennettsville, S. C., to Miss Elizabeth Ilderton in Charleston, October 6.

IRVIN HILARY GRIFFIN, Moundville, Ala., to Miss Mabry Griner of Tuscaloosa, September 18.

JOHN MARTIN IRVIN, Milwaukee, to Miss Virginia Van de Sand of Fulton, Ill., September 15.

FRANK L. PLACHTE, Los Angeles, to Miss Saralee Bender of Eureka, S. D., September 7.

NORMAN WILLIAM FRINK to Miss Kathryn Analdine Lee, both of Detroit, September 9.

ROY F. GARRISON to Miss Barbara Ummel, both of Kansas City, Mo., September 3.

Deaths

Peter Bassoe ☼ Chicago, a leader in neurology and psychiatry, died at the Presbyterian Hospital, November 5, of coronary thrombosis, aged 71.

Dr. Bassoe was born in Drammen, Norway, May 18, 1874. He graduated at the Real-gymnasium, Oslo Kathedralskole, in 1892, coming to the United States the following year. In 1897 he graduated at the College of Physicians and Surgeons, School of Medicine of the University of Illinois, serving his internship at the Cook County Hospital. He had been assistant physician and pathologist at the Mount Pleasant (Iowa) State Hospital from 1898 to 1900 and assistant physician at the Worcester (Mass.) State Hospital, 1901-1902. He had served as professor of neurology at Rush Medical College from 1924 to 1941, having been a member of the faculty in various capacities since 1905. He was professor of neurology at Illinois from 1941 until his death.

Dr. Bassoe had been a member of numerous societies devoted to his specialty, including the American Neurological Association, Chicago Neurological Society, Chicago Pathological Society and the Institute of Medicine of Chicago, all of which he had served as president, the Association for Research in Nervous and Mental Disease and the Central Neuropsychiatric Association. He held honorary membership in the Medical Society of Norway, Medical Society of Sweden and the Minnesota Neurological Society. He was a member of the consulting staff of the St. Francis Hospital in Evanston and the Grant Hospital, a member of the board of directors of the Norwegian American Hospital and of the staff of the Swedish Covenant Hospital. He had been a member of the Presbyterian Hospital staff for a number of years, serving as chairman of the department of neurology there since 1942. Dr. Bassoe was chairman of the Section on Nervous and Mental Diseases of the American Medical Association from 1921 to 1922 and had been a member of specialty groups concerned with psychiatry development, including the Illinois Psychiatric Research Council, an early state committee to aid in the development and care of the mentally diseased, as well as of a special group created to study sex degeneracy. He had been contract surgeon of the neuropsychiatric board and member of the medical advisory board during World War I. His extensive writings included service as editor of the "Year Book in Nervous and Mental Diseases."

Clay Alder, Chicago; University of Illinois College of Medicine, Chicago, 1915; on the staff of the Augustana Hospital; died August 13, aged 58, of chronic myocarditis, decompensation and arteriosclerosis.

Marvin Eldon Arrington, Vaiden, Miss.: Tulane University of Louisiana School of Medicine, New Orleans, 1931; member of the American Medical Association; since July 1, 1933 part time health officer of Carroll County; died in the Greenwood-Leflore Hospital, Greenwood, August 8, aged 38, of injuries received in an automobile accident.

Isidor Phineas Behrman, Brooklyn; University and Bellevue Hospital Medical College, New York, 1905; member of the American Medical Association; on the staff of the Israel-Zion Hospital; died in the Park East Hospital August 4, aged 62, of carcinoma.

Benjamin Hoyt Belcher ☼ Yonkers, N. Y.; University and Bellevue Hospital Medical College, New York, 1904; director of the venereal disease clinic of the city department of health; on the staff of St. Joseph's Hospital, Yonkers General Hospital, Yonkers Professional Hospital and St. John's Riverside Hospital, where he died July 31, aged 66, of cardiac failure following perforated duodenal ulcer.

James Clark Berry, Shadyside, Ohio; Starling Medical College, Columbus, 1901; died July 30, aged 73, of coronary thrombosis.

James M. Brady ☼ St. Louis; St. Louis College of Physicians and Surgeons, 1898; associate professor of pediatrics emeritus at the St. Louis University School of Medicine; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics; fellow of the American College of Physicians; served on the staff of the DePaul Hospital; died September 6, aged 68, of chronic myocarditis.

Prentiss Agnew Brown ☼ New Kensington, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1896; member of the Radiological Society of North America, Inc.; one of the founders of the Citizens General Hospital and a director of the Logan National Bank and Trust Company; died July 19, aged 70.

William Culp Brown, Oak Park, Ill.; National Medical University, Chicago, 1895; also a dentist; died in the West Suburban Hospital August 1, aged 79, of chronic interstitial nephritis and chronic myocardial degeneration.

William Simon Brown ☼ Elgin, Ill.; College of Physicians and Surgeons of Chicago, 1894; served in the medical corps of the U. S. Army during World War I; on the staff of the American Hospital, Chicago, St. Joseph Hospital and for many years chief of staff of the Sherman Hospital, where he died August 17, aged 77, of coronary thrombosis.

Joseph V. Capel, Harrisburg, Ill.; University of Louisville Medical Department, 1893; St. Louis College of Physicians and Surgeons, 1894; member of the American Medical Association; president of the Harrisburg National Bank; died August 7, aged 78, of cerebral hemorrhage.

Chester Harlan Clark, Wells, Nev.; University of Missouri School of Medicine, Columbia, 1904; on the courtesy staff of Elko (Nev.) General Hospital, where he died July 23, aged 69, of coronary occlusion.

Henry Leo Crahan, Rutland, Vt.; University of Vermont College of Medicine, Burlington, 1903; member of the American Medical Association; served overseas as a captain in the medical corps of the U. S. Army during World War I; died in the Veterans Administration Facility, White River Junction, July 28, aged 66.

Fay E. Cramer, Hawthorne, Calif.; Creighton University School of Medicine, Omaha, 1924; served overseas during World War I; died August 6, aged 48, of cardiac thrombosis.

Alice Lavinia Kimball Darmond, Methuen, Mass. (licensed in Massachusetts in 1900 and New York in 1907); died June 24, aged 69, of carcinoma of the breast.

Cline Fleming Davidson ☼ Seattle; Johns Hopkins University School of Medicine, Baltimore, 1907; served during World War I; for many years endocrinologist at the Children's Orthopedic Hospital; on the staffs of the Swedish and Doctors hospitals; died July 21, aged 65, of coronary occlusion and Parkinson's disease.

Joseph Anthony Di Leo, Long Island City, N. Y.; Loyola University School of Medicine, Chicago, 1931; member of the American Medical Association; assistant attending surgeon at St. John's Hospital, where he died August 9, aged 39, of hypertensive heart disease.

William McGaughey Dofflerhide, Oak Grove, La.; Kentucky University Medical Department, Louisville, 1904; died July 12, aged 68, of carcinoma of the liver.

William H. Enos, Alton, Ill.; Pulte Medical College, Homeopathic, Cincinnati, 1880; died in St. Joseph's Hospital July 27, aged 90, of hypostatic pneumonia.

Valentine Benjamin Fischer, Boulder, Colo.; University of Colorado School of Medicine, Denver, 1909; served as regent at the University of Colorado from 1934 to 1940; member of the American Academy of Ophthalmology and Otolaryngology; served as a medical examiner on the county draft board during World War I; died in Estes Park August 3, aged 59, of coronary thrombosis.

Andrew Barron Fitzgerald, North Creek, N. Y.; University of Vermont College of Medicine, Burlington, 1912; died July 31, aged 58, of generalized arteriosclerosis.

William E. Gibson, Issaquah, Wash.; College of Physicians and Surgeons, Keokuk, Iowa, 1888; formerly mayor, member of the town council and state legislature; died June 28, aged 85, of senility.

John Gilbert, York, Pa.; Jefferson Medical College of Philadelphia, 1895; member of the American Medical Association; formerly school physician; died July 30, aged 77, of cerebral hemorrhage.

Abraham L. Greenberg ☼ Brooklyn; Fordham University School of Medicine, New York, 1919; specialist certified by the American Board of Urology, Inc.; member of the American Urological Association; fellow of the American College of Surgeons; on the staffs of the Beth-El and Brooklyn Jewish hospitals; died at Stamford, N. Y., July 15, aged 50, of coronary thrombosis.

Merton Lyman Griswold, Uxbridge, Mass.; University of Vermont College of Medicine, Burlington, 1896; member of the American Medical Association; died June 10, aged 77, of cerebral hemorrhage.

Russell LeRoy Guffey, San Francisco; Ohio State University College of Medicine, Columbus, 1920; died July 22, aged 52, of pneumonitis, asthma and acute dilatation of the heart.

Posey Dow Gum, West Plains, Mo.; Louisville (Ky.) Medical College, 1894; member of the American Medical Association; past president and secretary of the Howell-Oregon-Texas Counties Medical Society; on the staff of the Christa Hogan Hospital; president of the chamber of commerce; died in Kansas City July 10, aged 72, of hypostatic pneumonia.

Frederick Charles Harris, Cando, N. D.; Trinity Medical College, Toronto, Ont., Canada, 1895; formerly coroner and president of the board of health of Towner County; once a director of the North Dakota State Tuberculosis Sanatorium, San Haven; died September 15, aged 74, of coronary thrombosis.

George Tracy Haverfield, Uhrichville, Ohio; Starling Medical College, Columbus, 1907; died in the Twin City Hospital, Dennison, July 26, aged 63, of cerebral hemorrhage.

James Decator Henderson, Boyds Creek, Tenn.; Tennessee Medical College, Knoxville, 1891; Miami Medical College, Cincinnati, 1896; member of the American Medical Association and the Ohio State Medical Association; served in the medical corps of the U. S. Army during World War I; died in the Veterans Administration Facility, Mountain Home, July 8, aged 79, of disease of the central nervous system.

William Hindle @ Providence, R. I.; Harvard Medical School, Boston, 1903; member of the New England Pediatric Society; superintendent of the Charles V. Chapin Hospital, where he died July 26, aged 69, following an operation for thrombophlebitis of the popliteal vein.

Francis Roderick Holbrook @ Des Moines; University of Pennsylvania Department of Medicine, Philadelphia, 1904; president of the Polk County Medical Society in 1931; served in the medical corps of the U. S. Army during World War I; medical director of the Solar Aircraft Company; on the staffs of the Iowa Methodist Hospital and the Mercy Hospital, where he died July 25, aged 64, of multiple myeloma.

Gerry Rounds Holden @ Jacksonville, Fla.; Johns Hopkins University School of Medicine, Baltimore, 1901; served as president of the Florida Medical Association; member and past president of the Southeastern Surgical Congress; member of the Southern Surgical Association and the South Atlantic Association of Obstetricians and Gynecologists; fellow of the American College of Surgeons; consulting gynecologist, Flagler Hospital, St. Augustine, and St. Luke's and Duval County hospitals; died July 21, aged 70.

Thomas Milton Holmes @ Delmar, N. Y.; Albany Medical College, 1909; served as a member of the medical board of the State Employees Retirement System; received the Purple Heart for service during World War I; died July 15, aged 63.

Charles John Hufnagel @ Richmond, Ind.; University of Louisville Medical Department, 1914; president of the Wayne-Union Counties Medical Society; served two years in France during World War I; surgeon on the staff of the Reid Memorial Hospital; died in Chicago July 22, aged 55, of coronary occlusion.

Thomas Lee Hutton @ Hartsburg, Ill.; Barnes Medical College, St. Louis, 1908; died in the Deaconess Hospital, Lincoln, July 20, aged 66, of heart disease.

James Marcus Jackson New Salem, Pa.; Harvard Medical School, Boston, 1900; Western Pennsylvania Medical College, Pittsburgh, 1902; member of the American Medical Association; died July 4, aged 68.

Edwin Brown Jenks @ Diamond Point, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1901; died July 17, aged 68, of coronary thrombosis.

Roland Joseph Joyce Nashua, N. H.; Tufts College Medical School, Boston, 1920; member of the American Medical Association; served as president of the Hillsborough County Medical Society; on the staffs of St. Joseph's and Memorial hospitals; died in the Phillips House, Boston, July 8, aged 49, of malignant tumor of the brain.

John W. Kramps, Chicago; Rush Medical College, Chicago, 1898; on the staffs of the Alexian Brothers' Hospital, St. Anne's Hospital and St. Elizabeth Hospital, where he died August 16, aged 77, of arthritis and heart disease.

Samuel Leventhal @ Brooklyn; Long Island College Hospital, Brooklyn, 1923; associate physician at the Bushwick and Lutheran hospitals; died July 11, aged 48, of carcinoma of the lung.

Edwin G. Low, Bangor, Mich.; Chicago Homeopathic Medical College, 1898; member of the American Medical Association; on the staff of the Borgess Hospital in Kalamazoo; died July 12, aged 84, of carcinoma of the large intestine.

Charles McDowell, Brooklyn; New York Homeopathic Medical College, 1878; member of the board of trustees and emeritus professor of physiology and public health at his alma mater, now known as the New York Medical College, Flower and Fifth Avenue Hospitals; died in St. John's Hospital August 31, aged 87, of toxemia following a fractured hip incurred in a fall.

John Henry Molinelli @ West Pittston, Pa.; Regia Università di Torino Facoltà di Medicina e Chirurgia, Turin, Italy, 1900; vice president and director of the Liberty National Bank in Pittston; on the staff of the Pittston (Pa.) Hospital, where he died July 21, aged 71, of cardiorenal disease.

Abraham Lear Morris, Chicago; Bennett Medical College, Chicago, 1912; member of the American Medical Association; died in the Woodlawn Hospital July 27, aged 62, of cerebral hemorrhage.

Millard Tarsten Nelsen @ Tacoma, Wash.; Washington University School of Medicine, St. Louis, 1921; member of the Pacific Coast Surgical Association and the North Pacific Surgical Association; fellow of the American College of Surgeons; member of the surgical staff, Tacoma General and St. Joseph's hospitals; attending surgeon, Pierce County Hospital; consulting surgeon, Veterans Administration Hospital, American Lake; died July 2, aged 47.

Harry Ostrer, Boston; Middlesex College of Medicine and Surgery, Cambridge, 1923; died July 16, aged 52, of cerebral thrombosis.

William Anneslay Patterson, Gansevoort, N. Y.; University of the City of New York Medical Department, New York, 1887; died July 25, aged 83, of fractured hip due to a fall, arteriosclerosis and pernicious anemia.

Maurice Mesha Perlson, Milwaukee; Marquette University School of Medicine, Milwaukee, 1927; served as school physician; formerly on the staff of the Mount Sinai Hospital; died July 25, aged 43, of coronary thrombosis.

John William Primrose, Clarksdale, Miss.; Memphis (Tenn.) Hospital Medical College, 1902; member of the American Medical Association; on the staff of the Clarksdale Hospital, where he died July 16, aged 65, of mitral regurgitation.

Thomas Ennis Pugh, Kansas City, Kan.; Atlanta Medical College, 1914; member of the American Medical Association and the Medical Association of Georgia; served with the British government during World War I; formerly on the staffs of various Veterans Administration facilities; died in the University of Kansas Hospitals July 18, aged 51, of tuberculosis.

Rezin J. Pumphrey, Lake Worth, Fla.; Cincinnati College of Medicine and Surgery, 1885; fellow of the American College of Surgeons; formerly on the staff of the City Hospital in Massillon, Ohio; died in West Palm Beach July 20, aged 83, of nephrosclerosis and arteriosclerotic heart disease.

Hauphrey Helm Sherwood @ Kirkland, Wash.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901; died in Seattle July 2, aged 73, of coronary disease.

Joseph Arthur Smith, Athol, Mass.; Boston University School of Medicine, 1898; for many years school physician; served for several terms on the school board; a member of the draft board during World War I; died July 17, aged 70.

John Stile, Alturas, Calif.; Cooper Medical College, San Francisco, 1900; served as health officer of Modoc County; died in the Woodland Clinic Hospital, Woodland, July 13, aged 69.

William Sylvester Streker @ Providence, R. I.; Jefferson Medical College of Philadelphia, 1908; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; on the staff of St. Joseph's Hospital; died in Barnstable July 8, aged 59, of coronary thrombosis.

Robert John Styers, Amelia C. H., Va.; University College of Medicine, Richmond, 1911; member of the American Medical Association; served overseas during World War I; died in the Stuart Circle Hospital, Richmond, July 24, aged 59.

Wallace Henry Tarbell @ Contoocook, N. H.; University of Vermont College of Medicine, Burlington, 1902; served as health officer and member of the school board; on the staffs of the Margaret Pillsbury General and New Hampshire Memorial hospitals in Concord; died July 20, aged 73, of coronary thrombosis.

Adrian Langley Zemmer, Port Huron, Mich.; Wayne University College of Medicine, Detroit, 1934; member of the American Medical Association; accidentally drowned July 8, aged 40.

Correspondence

THE INCIDENCE OF DIABETES

To the Editor:—The article by Spellberg and Leff on the incidence of diabetes and glycosuria in inductees (*THE JOURNAL*, September 22, p. 246) will be welcomed by every one interested in the incidence of the disease. Such surveys should be carried out still more extensively.

May I comment on the reference of the authors to my Arizona experience? Having noted that in 1937 the diabetic mortality in New York was 42 and in Rhode Island 36.9 but in Arizona only 10 per hundred thousand, with the cooperation of the doctors in Arizona a study was made of the morbidity of diabetes in that state. Whereas mortality records showed great differences between Rhode Island and Arizona, when we made a survey of the state it was found that the morbidity was approximately the same in the two states (see Joslin, E. P.: *The Universality of Diabetes*, *THE JOURNAL*, Dec. 14, 1940, p. 2033).

Some of the findings were as follows: 1. Whereas Jews made up 0.5 per cent of the inhabitants of Arizona, they comprised 2 per cent of the total with diabetes (755). 2. Deaths of Indians from diabetes averaged 2 per year for the six years 1934 to 1939, but in the survey 73 Indians with diabetes were discovered or approximately the same percentage of all the diabetic as of Indians in the whole population. 3. In the prison and in the mental hospital in Arizona more diabetic inmates were found proportionately than in similar institutions in the East and more than would be expected by the National Health Survey. 4. Diabetes was acknowledged by 1 in 42 doctors of 334 reporting in Arizona and by 1 in 36 of 393 reporting in Rhode Island. 5. In the state as a whole there were 755 diabetic patients reported by the 290 doctors, who stated that they had or had not diabetic patients in their care, or 2.8 per doctor.

Diabetes is universal. The incidence is highest where (1) the average age is oldest, (2) women predominate, (3) obesity is most frequent, (4) the proportion of Jews is greatest, (5) medical supervision is closest and (6) deaths are most accurately reported.

ELLIOTT P. JOSLIN, M.D., Boston.

SULFATHIAZOLE IN PLASTIC VEHICLE

To the Editor:—A review of the article by Draeger and Pijoan on Treatment of Impetigo Contagiosa with Sulfathiazole in an Alcoholic Plastic Vehicle (*THE JOURNAL*, August 11, p. 1096) fails to reveal any mention of a control series of treatment with the vehicle minus the sulfathiazole. This a serious defect. Clinicians have recognized for decades the feasibility of successful treatment of impetigo contagiosa by occlusive dressings alone. It is important to have the authors indicate in a supplementary report the results in impetigo contagiosa of application of their alcoholic plastic vehicle without sulfathiazole.

On the basis of insufficient clinical study, liquid provi-nol acetate dressing inhibits growth of pus forming bacteria on the skin surface and in superficial injuries. Application of 55 per cent ethyl alcohol is also known to be a deterrent to bacterial growth. Its equivalent was the major vehicle of the alcoholic plastic vehicle of Draeger and Pijoan.

HERMAN GOODMAN, M.D., New York.

[On receiving a copy of Dr. Goodman's communication, Captain Draeger replied:]

To the Editor:—The emphasis which Lieutenant Pijoan and I intended to place in our paper was on the vehicle and its convenience, not on the incorporated sulfathiazole. Sulfadiazine in dimethoxy cellulose was used without alcohol in an aqueous medium for the treatment of impetigo (*Southwest. Med.* 27:118

[May] 1943) and in the treatment of burns and other infections (*Bull. Johns Hopkins Hosp.* 69:217 [Aug.] 1941; 71:304 [Nov.] 1942). In these reports the dimethoxy cellulose was dissolved in water and not in alcohol. The introduction of alcohol was not for its therapeutic action but rather to increase the drying rate, a practical point in convenience. However, dimethoxy cellulose apparently did limit the spread of the infection. In this light the conclusion which we expressed may be considered as not well worded.

R. H. DRAEGER, CAPTAIN (MC), U. S. Navy.

DOCTORS' MARK

To the Editor:—The subject discussed by Dr. Ronchese in his article "Personal Identification" in the July 28 issue of *THE JOURNAL* is very interesting, and the article itself is excellent. However, in his discussion of the signs or stigmas, of the various trades and professions I found no reference to the one that often identifies the physician. This consists of an obvious bony swelling over the dorsal surface of the middle phalanx of the middle finger of the left hand, the result of repeated percussion during examinations of patients' hearts and lungs.

FRANK COLE, M.D., Duluth, Minn.

Director, Department of Anesthesiology, St. Mary's Hospital.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in *THE JOURNAL*, Nov. 10, page 766.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Mar. 19-21. Sec. Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.

CONNECTICUT: * Endorsement. Hartford, Nov. 27. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven.

DELAWARE: Examination, Dover, Dec. 12. Endorsement, Dover, Dec. 19. Sec., Medical Council of Delaware, Dr. J. S. McDaniel, 229 S. State St., Dover.

FLORIDA: * Jacksonville, Nov. 26-27. Sec., Dr. Harold D. VanSchaick, 2736 S. W. Seventh Ave., Miami 36.

IDAHO: Boise, Jan. 15. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.

KANSAS: Topeka, Dec. 6. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. Seventh St., Kansas City 10.

KENTUCKY: Louisville, March 25-27. Sec., State Board of Health, Dr. Philip E. Blackerby, 620 S. Third St., Louisville 2.

MARYLAND: Medical, Baltimore, Dec. 11-15. Sec., Dr. J. T. O'Mara, 1215 Cathedral St., Baltimore. Homeopathic, Baltimore, Dec. 11-12. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, Nov. 20-23. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston.

NORTH DAKOTA: Grand Forks, Jan. 1. Sec., Dr. G. M. Williamson, 415 S. Third St., Grand Forks.

OKLAHOMA: * Oklahoma City, March 23. Sec., Dr. J. D. Osborn Jr., Frederick.

OREGON: * Jan. 23-26. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland 4.

PENNSYLVANIA: Harrisburg, January. Act. Sec., Bureau of Professional Licensing, Department of Public Instruction, Mrs. M. G. Steiner, 351 Education Bldg., Harrisburg.

SOUTH DAKOTA: * Pierre, Jan. 15-16. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.

VERMONT: Burlington, March or April 1946. Sec., Dr. F. J. Lawless, Richmond.

WISCONSIN: * Madison, Jan. 8-10. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

OKLAHOMA: Oklahoma City, Jan. 21. Sec., Dr. J. D. Osborn Jr., Frederick.

SOUTH DAKOTA: December. Sec., Dr. J. D. Alway, Aberdeen.

WISCONSIN: Milwaukee, Dec. 1. Sec., Prof. Robert N. Bauer, 152 W. Wisconsin Ave., Milwaukee.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

30:109-214 (Aug.) 1945

- Alteration in PR Interval Associated with Change in Posture. G. W. Manning and C. B. Stewart.—p. 109.
- Congenital Heart Disease: Case Reports on 3 Members of Family. I. Stein and D. J. Barber.—p. 118.
- Strain of Pectoralis Minor Muscle, Important Cause of Preordial Pain in Soldiers. M. Mendlowitz.—p. 123.
- Oral Single-Dose Digitalization with Digitalis Leaf and Digitaline "Nativelle." L. N. Katz and W. Wise.—p. 125.
- Cardiac Aneurysm with Rupture. R. L. Fisher.—p. 133.
- Electrocardiogram in Hypertension: I. Its Description. E. Evans, Marion Mathews and P. D. White.—p. 140.
- Id.: II. Effect of Radical Lumbodorsal Sympathectomy (Preliminary Report). P. D. White, R. H. Smithwick, Marion W. Mathews and E. Evans.—p. 165.
- Id.: III. Electrocardiograms of Hypertensive Patients Followed for a Long Time Without Splenectomy Resection in Comparison with Those in Patients Who Had Had Splenectomy Resection. E. Jacquin Canale, H. F. Warneford-Thomson and P. D. White.—p. 189.
- *Clinical Observations with Cerberin. G. Bond, H. Baum and G. Diamond.—p. 194.

Clinical Observations with Cerberin.—Bond and his associates felt that the effect of cerberin, an extract from the kernel of *Cerbera odollam*, a tree native of India and the Dutch East Indies, could best be demonstrated in patients with auricular fibrillation. They selected patients who had not received previous digitalis medication. On admission each patient was given complete rest in bed, with sedation if necessary, for eighteen to twenty-four hours, and in 2 cases as much as ten days' rest in bed was maintained before medication was begun. This was done to discount the effect of rest on the fibrillation before the drug was given. In the first 10 cases cerberin was given intravenously, while in the last 5 an oral preparation was used. Fourteen of the 15 patients treated with the drug had auricular fibrillation and 1 was in congestive failure with a regular rhythm. Auricular fibrillation was controlled satisfactorily with the intravenous or oral use of cerberin. Its effect is much more rapid than that of digitalis and more transitory after the drug is discontinued. No untoward effects were noted when therapeutic doses were used.

American Journal of Clinical Pathology, Baltimore

15:203-304 (July) 1945

- Spinal Fluid Protein and Colloidal Mastie Tests. L. E. A. Fennel.—p. 203.
- Plasma Vitamin A Level in Renal Diseases. H. Popper, E. Steigmann and Hattie A. Dymiewicz.—p. 272.
- Production of Rh Antisera in Guinea Pigs Through Inoculation with Human Red Blood Cells. Hettina B. Carter.—p. 278.
- Observations on Sensitization to Rh Factor by Blood Transfusion. L. J. Unger and A. S. Wiener.—p. 280.
- Pathology of Anemia in Rh Negative Patient. V. J. Dardziński.—p. 286.
- *Food Poisoning: Importance of Method of Presentation of Medicolegal Evidence. H. A. Heise.—p. 289.
- Determination of "Sulfate Index" as Measure of Degree of Exposure to Benzene Vapor. W. S. Hoffman and Bess Osgood.—p. 293.
- Association of Aorta with Congenital Bicuspid Aortic Valve and Dissecting Aneurysm of Arch of Aorta. R. B. Lewis.—p. 297.

Food Poisoning.—Heise describes a case of food poisoning involving legal action against a food distributing company. The offending food was a salad containing canned sea foods, macaroni, mayonnaise and celery. A medical witness for the complainant contended that the sea food was the most likely source of contamination and that this contamination occurred before

the cans were opened. In presenting medical testimony for the defense, a salad was prepared according to the method used in making the original salad, and this salad was then tested for bacterial contamination. The experiment indicated that the celery and the mayonnaise were possible sources of contamination. The actual cultures of the ingredients of the salad, as well as cultures of the salad itself made at various times, failed to impress a jury and the canning company was adjudged guilty. However, a supreme court which reviewed the evidence including photographs of the cultures reversed the decision and dismissed the case.

American Journal of Medical Sciences, Philadelphia

210:141-280 (Aug.) 1945

- Comparison of Behavior of Microcrystalline Sulfadiazine with That of Ordinary Sulfadiazine in Man. J. G. Reinhardt, F. J. Phillips and H. F. Eppin, with technical assistance of Lillian Pollack.—p. 141.
- Penicillin—Its Present Status in Treatment of Infections. C. S. Keeler.—p. 147.

Early Filariasis in American Soldiers.—Hodge and his associates present observations on 62 soldiers who were diagnosed as having filariasis. The 62 cases of early filariasis are divided into five groups: Group 1 comprised 47 cases characterized by genital manifestations. The 13 patients of group 2 had superficial lymphangitis of the extremities. Sixteen patients of group 3 had multiple lesions. The patient designated as belonging to group 4 had symptoms suggestive of involvement of the deep lymphatics. The authors placed in group 5 asymptomatic cases with microfilariae in the blood; only 1 of their patients belonged to this group. Laboratory studies were fairly complete on 50 of the 62 clinical cases. These included complete blood counts, frequent differential leukocyte counts, examinations of the blood, aspirated fluids and urine for microfilariae. Histopathologic and bacteriologic studies were performed on several lymph nodes. Examination revealed microfilariae in only 2 of 200 soldiers exposed to filariasis. Eosinophilic infiltration was the most constant finding. The additional findings of fibroblastic proliferation, focal necrosis and lymphinization further suggest that the changes are due to an allergin. The authors believe that the early manifestations are due to an allergin present in or produced by living adult filariae. The clinical diagnosis is not dependent on the finding of adult filariae. Clinical manifestations may be multiple and are subject to recurrences. The prognosis must be guarded, but in the light of the present knowledge it appears to be favorable if reinfection is prevented. Some of the early cases may be carriers, and rigid mosquito control should be carried out until more is known regarding the status of these patients.

Tularemia Pneumonia.—Stuart and Pullen state that of the 208 cases of tularemia pneumonia available for study in the American literature (including 15 cases of their own) a history of contact with animals was available in 115. Only 171 of the 208 patients (63.8 per cent) had necroglanular, oenoglauhar or glandular types of the disease, whereas 97 cases (36.2 per

cent) had no demonstrable primary lesions or lymphadenopathy and may be classified as the typhoidal type of infection. Symptoms presented by patients with tularemia pneumonia fall into two general groups: In the first group the pneumonia is associated with the ulceroglandular, glandular or oculoglandular types of tularemia infection and may occur from one or two days to many months after the localized infection elsewhere has developed. In the second group, evidence of ulceration and lymphadenopathy is lacking. In these cases of typhoidal or cryptogenic type of tularemia the infection frequently appears to originate as a primary pneumonia, suggesting that the infection may have entered through the respiratory tract. In this group the onset may be sudden with a chill, fever, dyspnea, cough, pain in the chest and profuse sweating. The cough may or may not be productive. These patients appear extremely ill and are frequently suspected of having typhoid. The physical signs of tularemia pneumonia vary with the type and distribution of the lesions. Both lungs are frequently involved. In general the physical findings are those of an atypical pneumonia. Physical examination of the chest may reveal no abnormal findings even though pleuropulmonary involvement can be demonstrated roentgenographically. Hence, roentgenographic studies of the chest of any patient with tularemia are advisable. Of the 225 patients with tularemia observed at the Charity Hospital of Louisiana at New Orleans, 21 (9.33 per cent) had accompanying tularemia pneumonia. The incidence of tularemia pneumonia is distinctly greater in the typhoidal forms than in the ulceroglandular. Pleuropulmonary involvement developed in only 13 (7.1 per cent) of 181 cases of ulceroglandular tularemia, whereas clinical tularemia pneumonia developed in 8 cases of typhoidal tularemia. Of the 21 patients with tularemia pneumonia, 12 died. Although the incidence of tularemia in Negro patients as compared to white patients is proportional to the total admissions of white and Negro patients at Charity Hospital for the same period of time, it would seem that Negroes are particularly lacking in resistance once they have developed the pulmonary forms of the disease. This is evidenced by the fact that 16 of the 21 patients of tularemia pneumonia were Negroes and that 11 of these 16 patients died. Only 1 white patient died, and this may be attributed in part to an uncontrolled diabetes mellitus. In patients who recovered, the average duration of the pneumonia was thirty days.

Hypo-Ovarianism Treated with Gonadotropins.—Hauhlen, Davis, and their co-workers showed that cyclic administration of equine gonadotropin during the follicular phase of the cycle failed to result in progestational bleeding or in pregnancies in women who bled from interval or estrogenic endometriums, in many of whom ovarian sterility constituted a major problem. When a similar group of women was treated with the same equine gonadotropin but, in addition, was given injections of chorionic gonadotropin from the fifteenth through the

twenty-fourth day of their cycles there occurred a substantial number of progestational endometriums and a number of pregnancies. This therapeutic schedule was named one-two cyclic gonadotropic therapy. A total of 116 hypo-ovarian patients were treated by the sequential and cyclic administration of equine and chorionic gonadotropins. Only 1 of 7 patients with deficient sexual maturation and nonoccurrence of menarche (hypoestrogenism) yielded a progestational endometrium during therapy. Four of 13 patients with infrequent and/or scanty estrogenic uterine bleeding yielded progestational endometriums during therapy. Fifteen of 31 patients with prolonged and/or excessive estrogenic bleeding yielded progestational endometriums during therapy. Seven of 14 patients with cyclic estrogenic bleeding and ovarian sterility yielded positive responses, including 4 pregnancies. Nine of 50 patients with cyclic bleeding from immature progestational endometriums became pregnant during therapy. The following conclusions are reached: 1. Patients with hypoestrogenism (as illustrated by those with deficient sexual maturation) respond poorly to this system of gonadotropic therapy. 2. Patients with anovulatory ovarian failure without hypoestrogenism (as illustrated by those with diverse types of estrogenic bleeding) respond well to this system of therapy. A total of 44.8 per cent yielded progestational endometriums. 3. A small percentage of sterile women, whose bleeding from immature progestational endometriums constitutes the only significant finding, become pregnant when treated with one-two cyclic gonadotropic therapy.

Epidemic and Herpetic Keratoconjunctivitis.—Mammence and his associates report isolation and identification of two closely related but apparently different viruses obtained from the eyes of 6 patients with the typical clinical picture of epidemic keratoconjunctivitis. Material for mouse brain inoculation was obtained from the patients' eyes by washing the lower conjunctiva with 0.5 cc. of Simms's Z solution, which was collected and placed in sterile ampules. To the washings were added several scrapings from the conjunctiva made with a platinum spatula. The material was inoculated intracerebrally into mice, which were killed with gas as close as possible to the termination of their illness. The brains were removed and ground, and a 10 per cent emulsion was centrifuged. The supernatant fluid was pipetted off and either used immediately or frozen and stored. A portion of this supernatant fluid was cultured for evidence of chance bacterial contamination. Corneal inoculations were made in the rabbit by scarifying the corneal epithelium with a syringe needle and rubbing conjunctival scrapings taken from the patient's eye directly on the cornea. Passage material was obtained from the rabbits' eyes. It was found that herpes simplex virus can cause a keratoconjunctivitis which is clinically almost identical to that caused by the epidemic keratoconjunctivitis virus. In spite of the similarity in the clinical picture and the cross immunologic reactions of the two viruses, they are thought to be separate entities but are probably of the same genus. Intracellular inclusion bodies produced by the epidemic keratoconjunctivitis virus have been demonstrated experimentally for the first time. Methylthionine chloride therapy for herpes and epidemic keratoconjunctivitis appears to be of some value in the early stages of these diseases.

Hyperimmune Rabbit Serum in Western Equine Encephalomyelitis.—Fifty-five guinea pigs were treated with specific hyperimmune rabbit serum of 500 to 1,000 units when they became sick following intralingual injection of western equine encephalomyelitis virus. Of this number 67.3 per cent recovered. Of the 41 guinea pigs used as controls, 1 recovered spontaneously and 40 died. Serotherapy was less effective in rhesus monkeys, giving a recovery rate of 45.5 per cent against no recoveries in the control group. These animals were treated with serum at the onset of fever following intracerebral injection of the virus. By this method of injection the virus produces a fulminating type of the disease which is more difficult to treat. A western equine encephalomyelitis antiserum has been prepared by hyperimmunization of rabbits which is effective in treating the experimental disease even after the animals showed evidence of central nervous system involvement. It is believed that the successful treatment of the disease in these experiments can be attributed to the use of adequate quantities of antiserum of high potency administered by a route which made the serum antibodies readily available to the animal.

Penicillin in Pulmonary Suppuration.—Kullman and Crellin report 2 cases of lung abscess resulting from sulfonamide resistant *Streptococcus hemolyticus* pneumonia. They were successfully treated by parenteral penicillin therapy. In the first patient, who received a total of 3,020,000 units over a period of twenty-four days, the penicillin was given on the first day by continuous intravenous drip and thereafter in doses of 15,000 units at three hour intervals. The second patient received a total of 1,475,000 units over a period of fourteen days. These cases prove the absorption of penicillin through thin walled cavities when treated over a sufficient period of time. The sputum became negative for hemolytic streptococci in three and two days, respectively. Complete healing, demonstrated by roentgenogram, occurred in twenty-six and thirty-four days, respectively. Four patients with *Streptococcus hemolyticus* empyema were successfully treated by intrapleural injection of penicillin supported by intravenous and intramuscular use of the drug. Two of these patients were classified as sulfonamide resistant. The other 2 had had insufficient sulfonamide to be classified as such. The latter were moribund. Thoracotomy was obviated in all cases of empyema. No evidence of reinfection or recurrence has occurred in any of these cases. Aspirated pleural fluid remained sterile after twenty-four to thirty-six hours, when the intrapleural treatment was supplemented by intravenous and, later, by intramuscular penicillin. The patient receiving only intrapleural penicillin retained an infected pleural space until the sixth day after treatment was started. Success or failure

may depend on the supplemental parenteral administration of penicillin. Residual fibrosis and subjective slight dyspnea necessitated return to a limited duty status in 1 patient. The 3 other patients returned to a full duty status in 125, 126 and 151 days, respectively.

Complications Following Spinal Anesthesia.—Yaskin and Alpers report 6 instances of neuropsychiatric complications following spinal anesthesia. They also mention a case of metastatic spinal cord neoplasm which was discovered after spinal anesthesia in which the anesthetic agent was for a while suspected as being the cause of the myelitic syndrome. In 4 of the patients the complications occurred immediately following the use of the anesthetic agent. They presented syndromes of serious myelitic or myeloradicular nature. Little or no recovery occurred. Two of the reported cases were in the nature of conversion hysteria "paralysis" of the lower extremities. The conversion mechanism was conditioned by the patient's subjective experience with spinal anesthesia. The case of metastatic spinal cord neoplasm is presented to illustrate the importance of keeping in mind the possibility of preexisting neurologic disease when evaluating the role of spinal anesthesia in the causation of postoperative neurologic sequelae.

Wound Shock.—Stewart and Warner made clinical studies on 114 severely wounded soldiers admitted as nontransportable to forward field hospital units. These soldiers comprised a selected group in urgent need of resuscitation and surgical treatment. The variability in the clinical picture of wound shock gave the impression that the usual concepts in the definition of traumatic shock are too rigid. The mental and emotional state of the patient, pain, blood pressure, pulse rate, sweating, nausea and vomiting, extent of filling of peripheral veins, skin temperature and plasma volume all were elements subject to considerable variation. Reduction in plasma volume was the rule before replacement therapy. The volume of the whole blood was proportionately more depleted than that of the plasma. Initial deficits of hemoglobin are relatively greater than deficits of plasma protein and are less easily corrected. The validity of this observation is somewhat depreciated by the uncertain effects of plasma infusion and blood transfusions. With respect to administration of plasma and whole blood, it was repeatedly noted that quantitative changes do not result from such therapy. Depleted storehouses for plasma protein and hemoglobin have a high priority during restorative therapy, and hemoconcentration as evidenced by elevation of red cell hematocrit or plasma protein above normal ranges was not encountered in the absence of burns or complicating clostridial myositis. Despite restorative therapy, anemia and hypoproteinemia were the rule during convalescence. Quantitative improvements in blood volume and in concentration of plasma protein and hemoglobin did not occur in response to replacement of plasma and blood. No evidence of overdosage in plasma and whole blood therapy was detected. Dehydration and azotemia were common in early convalescence. In fulminating clostridial myositis

with edema, plasma protein concentration and blood volume fell rapidly. Erratic effects were obtained from sulfonamide therapy. There were 17 deaths among the 100 ground force casualties and 2 deaths among 14 patients with flak wounds.

Polycythemia as Neurosurgical Problem.—Drew and Grant direct attention to the frequency of lesions of the central nervous system in polycythemia. Of 62 patients with this condition at the Hospital of the University of Pennsylvania in the last fourteen years, changes of this nature ranging from facial weakness to complete hemiparesis or stupor have been present in 13. In a case in which a chronic subdural hematoma was associated with polycythemia the latter had disappeared after the removal of the hematoma but showed a tendency to return five months after the operation. Literature on the coincident occurrence of expanding intracranial mass lesions and polycythemia revealed 9 cases in which the diencephalic region was not involved. In another patient papilledema of a high degree was associated with polycythemia. The occurrence of a true expanding intracranial mass lesion with polycythemia is rare, but the coincidental occurrence of papilledema and polycythemia is somewhat more common. The cause and effect relationship between polycythemia and disease of the central nervous system is becoming increasingly well documented, but the volume of work done is not yet sufficient to warrant its being recognized as an established fact. Polycythemia with papilledema must be considered as a possible diagnostic and operative problem for the neurosurgeon.

Crutch Walking: Muscular Demands and Preparation.

—The five muscle groups needed particularly for manipulation of crutches are, in order of importance, (1) flexors of the arms to move the crutches forward, (2) extensors of the forearms to hold the elbows stiff, so that they do not buckle when the weight of the body is placed on the hands and when the body weight is raised from the floor, (3) finger and thumb flexors to permit grasping the crutches, (4) dorsiflexors of the wrist to keep the hands in the correct positions on the hand pieces and (5) shoulder girdle depressors and downward rotators to support the body by means of the crutches when it leaves the floor. Crutches are invaluable aids toward attaining better balance and locomotion. Preparation for crutch walking includes a muscle test to discover the extent of muscular weakness, an exercise program to develop strength in the muscle groups necessary for crutch walking and instruction in how to stand and balance with crutches before taking any steps. For patients who will use crutches, it is good medical practice to prescribe an exercise program for the specific muscle groups used in crutch walking. The exercises are grouped as (1) bed or mat exercises, (2) wheel chair exercises, (3) mat exercises, (4) standing exercises with a bar or any other support, (5) walking exercises with support other than crutches and (6) standing exercises with crutches. Deaver and Brown stress that these exercises are elementary and should be learned by every one who plans to use crutches for an indefinite period. Other crutch balancing exercises should follow these, but they differ according to the crutch gait to be used.

Hydrocephalus Caused by Strictures of Aqueduct of Sylvius.—According to Dandy, the diagnosis of a stricture at the aqueduct is simple in infants. If the dye test (phenolsulfonphthalein) shows an obstruction in the ventricular system, the obstruction will be either at the aqueduct or at the foramina of Magendie and Luschka. If theinion is low, the obstruction is at the aqueduct. The height of theinion is all important. For children over 1 year old the diagnosis can now usually be made by ventriculography and without operation and frequently without ventriculography. In most of these a partial occlusion of the aqueduct has doubtless existed long before becoming complete. An oversized head, with MacEwen's sign (cracked pot sound) and aninion normally placed or at times lower than normal, indicates hydrocephalus without a space-occupying lesion (a tumor) in the posterior cranial fossa. By exclusion, the lesion is a stricture of the iter of Sylvius. When ventriculography is used, the shape of the shadow in the aqueduct of Sylvius—funnel shaped or triangular—will frequently make the diagnosis without an unnecessary cerebellar operation for its disclosure. A third ventriculostomy by the temporal approach is the operation of choice for hydrocephalus due to a stricture of the aqueduct. It is much superior to the anterior approach because (1) external hydrocephalus does not follow, (2) it is not necessary to section a nerve (the optic nerve must be sectioned in the anterior approach) and (3) the scar is under the hair. Cures are attained in most cases when the patient is more than a year old, but in infants a perfect result is obtained in very few cases. One may question the wisdom of operating on this group, though operation is probably worth while when the head is not over 50 or 52 cm. in circumference at the time of operation.

Nitrogen Balance in Patients Receiving Amino Acids.

—Kozoll and his associates used parenteral injections of amino acids as the only source of protein during a study of nitrogen balance in 14 cases of obstructing lesions of the esophagus or stomach. Positive nitrogen balance was achieved in 13 of the 14 cases. The quantity of amino acids required by parenteral injection for positive nitrogen balance usually varied between 60 and 90 Gm. per day. At times doses of 120 Gm. were more successful in producing larger positive balances. The serum protein concentration rose during treatment in 4 cases, remained stationary in 2 and fell in 8. The serum albumin concentration rose in 6 cases and declined in 8. The following factors may have been involved in the failure of the serum protein to rise in response to the attainment of positive nitrogen balance: (a) Hemodilution, which occurred in most of the cases, masks an increase in serum protein. (b) The severity of the protein deficiency in the type of cases studied here may be so severe as to require a much longer period of positive nitrogen balance before the entire protein deficiency can be rectified. (c) Gain in nitrogen may be used up in the growth of metastases from carcinoma. (d) The albumin synthesizing mechanisms of the body may be interfered with by the presence of carcinoma with hepatic metastases or by a severe protein deficiency of the liver. Therapy with parenteral injections of amino acid should be

accompanied with an effort to meet the requirements of carbohydrate, minerals and vitamins. A minimal daily carbohydrate intake of 300 Gm should be assured. Therapy with parenteral injections of amino acid is only partly successful when the nitrogen losses are excessively high, since in such circumstances it is impossible to inject the required amounts of amino acids. In clinical practice two adjuncts to enhance the effects of therapy with parenteral injections of amino acid are recommended: (a) oral, intragastric or transgastric feedings of protein or amino acids and (b) transfusions of whole blood.

Isolation of Thromboplastin from Lung Tissue. W. H. Howell—p. 295.

Pulmonary Embolism—Hampton and his associates report 10 cases in which acute chest conditions are thought to have been caused by pulmonary embolism, with or without infarction, or with incomplete infarction, from various venous sources. The patients were at work, had no heart disease and gave no history of known phlebitis. A possible exception may be noted in case 8, in which a thrombosing hemorrhoid was noted at the time of the acute chest episode. None of the patients were admitted with a correct diagnosis. Phlebograms, roentgenograms and electrocardiograms are helpful in diagnosis. Such tests should be employed when a relatively dry area of consolidation is found in the lungs without specific bacteriologic findings, and in which dyspnea or chest pain is an important symptom. The onset may be insidious or it may closely simulate coronary occlusion, pneumonia, angina pectoris or pericardial effusion, in 1 case the roentgenogram resembled that of metastatic carcinoma. Cases of repeated "pleurisy" or "pneumonia," especially if bilateral, should be suspected of being due to pulmonary embolism. Probable sources of emboli have been found in leg veins, pelvic veins, thrombosed hemorrhoidal veins and veins of the prostatic and periprostatic plexus. In certain cases the source may remain unidentified. The authors have used heparin and dicumarol anticoagulant therapy plus rest and elevation of the part affected by thrombosis or phlebitis. They have not observed embolism after institution of such treatment.

Cold Agglutinins—Tests for cold agglutinins using erythrocytes from normal group O donors, were carried out by Finland and his associates on 1,069 subjects, including healthy persons and patients with a variety of conditions, mostly respiratory tract infections. Cold agglutinins in titers of 40 or higher were found in 137, or 68.5 per cent, of 200 characteristic cases of primary atypical pneumonia of unknown etiology, in 5 of 11 cases in which this was the probable diagnosis and in 4 of 7 cases of various kinds of hemolytic anemia. In only 10 or 12 per cent of the remaining 851 cases were cold agglutinins demonstrated in similar titer. In some of these 10 cases and of the few others in which cold agglutinins were demonstrated in lower titers, atypical pneumonia may have played a part. It is suggested that the development of cold agglutinins is related to the causative agent of primary atypical pneumonia and may serve as a diagnostic aid in this disease.

Antistreptolysin Titers in Filariasis—Rose and his co-workers determined antistreptolysin titers in the blood of 45 soldiers suffering from recurrent lymphangitis associated with filariasis contracted in the South Pacific. The titers were within

normal limits in 39 of the 45 cases. The attacks of lymphangitis in these soldiers appeared to be due to allergic reactions to the parasitic infection; secondary streptococcal infections were of little or no consequence as an etiologic factor.

Penicillin in Lobar Pneumonia.—Tillett and his associates report the results obtained in 110 cases of pneumococcal pneumonia treated with penicillin. There were 7 fatalities in this group, a mortality of 6.3 per cent. Among the patients who recovered, the effectiveness of penicillin was deemed definite in 93 and equivocal in 10 cases. Bacteremia, which occurred in 40 of the patients (36.3 per cent), was successfully eliminated. This result constitutes one of the most striking effects of penicillin therapy in pneumonia. The total amounts of penicillin employed have ranged from 120,000 to 200,000 units in cases of moderate severity and from 150,000 to 400,000 units in serious cases, depending on the evidence of response noted in the first twenty-four to forty-eight hours of treatment. In 3 instances infections caused by sulfonamide fast pneumococci were effectively treated with penicillin. No toxic reactions referable to penicillin have been noted.

Detection of Rh Sensitization.—Employment of a reliable method of detecting Rh antibodies is an important aid in the management of pregnancies of Rh negative women whose husbands are Rh positive. Diamond and Abelson evaluate the following tests for the detection of Rh sensitization: (1) the biologic test, (2) the modified compatibility or tube-agglutination test, (3) the "blocking" test, (4) the capillary tube test and (5) the open slide test. The biologic test possesses very limited clinical usefulness and should be used not to supplant but rather to supplement the *in vitro* methods. Of the latter the open slide test, when used alone, is by far the simplest and most reliable. It is particularly valuable as a screening test in following obstetric patients and as a confirmatory test for compatibility of blood donor and recipient. For a more refined diagnosis the tube-agglutination and blocking tests used in conjunction with each other possess a high degree of reliability and yield valuable information concerning the stage of immunization to which the sensitized patient has progressed.

Pneumococcal Meningitis in Children.—Hartmann and his associates review the clinical, laboratory and postmortem studies of all cases of pneumococcal meningitis admitted to the St. Louis Children's Hospital from the time the first sulfonamide drug was available for treatment (December 1936) to Nov. 1, 1944. The following conclusions have been reached: Apparently any type of pneumococcus may cause meningitis. The pathway by which the pneumococcus may gain entrance to the meninges and spinal fluid varies and should whenever possible be established because of its possible surgical implications. The incidence of "surgical" mastoiditis as a port of entry is much greater than in meningococcal but also apparently much smaller than in hemolytic streptococcus infections. When the temporal bone is involved there seems to be a characteristic pathologic picture which includes (1) a high incidence of purulent labyrinthitis, (2) the formation of "empyemic membrane," (3) peculiar organization of bubbly exudate which leads to pseudogland formation and (4) a high incidence of bilateral involvement. A diagnosis of pneumococcal meningitis can be made with certainty only by lumbar puncture and proper examination of the spinal fluid. The great value of early diagnosis far outweighs any theoretical danger imposed by lumbar puncture. Treatment should be started as early as possible with penicillin and sulfonamide in high dosage. Mortality seems more related to delayed diagnosis and institution of intensive therapy than to any other single factor. Sequelae such as hydrocephalus, epilepsy and mental retardation may be expected, especially when the infection occurs during infancy and is not eradicated immediately.

Action of Oils on Tubercle Bacilli.—Crimm and Martos report experiments in which Long's synthetic medium, Corper's egg medium and glycerol-peptone agar were used for culturing various strains of tubercle bacilli. The bacteriostatic action of peanut oil, cod liver oil and gomenol for the H₂ strain and the bovine and avian types of *Mycobacterium tuberculosis* was determined. It was found that peanut oil is inhibitory for H₂ and other virulent human strains in a concentration of 5 per cent and for the bovine type in a concentration of 2 per cent. For the avian type the limit of tolerance was not determined, but it is greater than a concentration of 10 per cent. Cod liver oil is bacteriostatic for the human, bovine and avian types of *Mycobacterium tuberculosis* in 1 per cent concentration. Gomenol is bacteriostatic for both human and avian types of *Mycobacterium tuberculosis* in 5 per cent concentrations. Complete inhibition of the bovine type occurred in 1 per cent concentration. Prolonged incubation of the H₂ strain and a virulent human strain isolated in this laboratory with peanut oil, cod liver oil and gomenol does not alter the virulence or the acid fastness of the organisms, although the colony morphology is altered. This observation

that the virulence of the tubercle bacillus is not altered by the oils differs from the results obtained by other investigators. The oils available today are more highly purified than those of a decade ago and have been freed from the substances responsible for the bacteriolytic action. The authors concur that these oils have an inhibitory action on the growth of the tubercle bacillus. However, the subsequent growth of the organisms on a rich medium and their normal virulence when injected into guinea pigs indicate that the oils adherent to the tubercle bacilli inhibit their growth by a physical rather than by a chemical action.

Vitamin C in Chest Surgery.—Zerbini studied the amount of vitamin C in the blood and the tissues of patients with chronic surgical diseases of the lung and esophagus. Twenty-two patients were studied before and after operation. The average ascorbic acid content found just after the admission of the patients was 0.15 mg. per hundred cubic centimeters. In 1 patient with a normal plasma ascorbic acid level before operation this level declined to practically zero after operation. In other cases an attempt was made to raise the plasma ascorbic acid level before and after operation so as to aid in the scar formation. The patients were given 1,000 mg. of ascorbic acid in a single period of twenty-four hours. This was divided into small doses of 100 mg. at a time. In a typical case it was seen that in twenty-four days of postoperative observation the level in the plasma was progressively increased to 0.85 mg. per hundred cubic centimeters, which is almost the normal level. The increase of ascorbic acid in the plasma was slow, although large doses were employed. The determination of the ascorbic acid in the white cells and platelets gave different results in different patients. When the general condition was good and the patient was a good risk, the white cell and platelet level did not change with the operation, even when the plasma level was zero. In 1 patient with esophageal cancer and artificial alimentation through a gastrostomy, the plasma and the white cells and platelets were both found deprived of ascorbic acid, a condition which represents a prescorbutic state. The amount of ascorbic acid in muscle and lung tissue removed during the operation seems to be below the values considered normal. It is concluded that every patient with a chronic surgical chest condition should be given high doses of ascorbic acid before and especially after important surgical procedures.

Ligation of Inferior Vena Cava for Prevention of Pulmonary Embolism.—Gaston and Folsom assert that necropsies disclose that in a high percentage of cases of pulmonary embolism the emboli originated in veins that were direct or indirect tributaries of the inferior vena cava. Ligation of the inferior vena cava below the level of the renal veins, although an operation of some magnitude, is compatible with recovery in seriously ill patients. Caval interruption is effective in preventing the embolic sequelae of thrombosis of the pelvic veins, whether this thrombosis is primary in the pelvic veins or secondary to a propagating thrombophlebitis originating in the veins of the legs. Even following ligation of the common femoral veins an adequate collateral circulation develops around the obstructed cava, and peripheral edema eventually disappears. The authors report 2 cases in which caval interruption effectively prevented further pulmonary infarction. The operation was followed by complete recovery in each case. Most helpful in sustaining the patient through the critical postoperative period were swathing the feet, legs and thighs tightly in elastic bandages to help prevent shock due to the rapid withdrawal of edema fluid from the circulation, the early use of oxygen and adequate intravenous infusions of plasma and whole blood.

Hazards of Transfusion Malaria After War.—Rubenstein and his associates state that, of the 12 cases of post-transfusion malaria reported in Massachusetts since 1929, all but 3 were quartan. The predominance of quartan infections is evidence that in a nonendemic area the problem of post-transfusion malaria is intimately linked with the ability of Plasmodium malariae to remain latent for long periods. Because several weeks may elapse between the transfusion and the onset of malaria in the recipient, the causal relations of these events may not be recognized. Post-transfusion malaria when recognized and promptly treated is not usually fatal.

Therapy in Clinical Hyperthyroidism.—Puppel and his associates found that calcium, phosphorus and vitamin D medication is of value in the treatment of clinical hyperthyroidism. Especial attention must be given to calcium, which in the usual diet is barely sufficient for a normal person. Hyperthyroid patients require about 2 Gm of calcium daily to maintain them in calcium retention. This is at least twice the optimum calcium requirement for normal adults. Three Gm daily is a more adequate amount to restore the depleted calcium. Phosphorus requirements are similarly increased. Eleven hyperthyroid patients maintained on a low intake of calcium, averaging 474 mg per day over a period of ninety days, showed an average loss of 459 milligrams per day. When 5 of these patients were further investigated on an adequate intake of calcium averaging 2,410 mg per day over a period of eighty-one days, remarkable retention of calcium occurred which resulted in a positive balance of 362 mg. per day. The state of the phosphorus balance showed similar spectacular and beneficial changes. Retention occurred whether the calcium was fed or administered parentally. The authors supplemented high calcium and high phosphorus diets with four of the most common types of calcium salt. They were all effective in maintaining retention of calcium and phosphorus. However, 3 of the 11 patients received added amounts of phosphorus and vitamin D besides the added amounts of calcium in the form of dicalcium phosphate with viosterol. The latter seemed to promote increased retention of calcium of 200 to 1,000 per cent over that of patients receiving only added calcium or calcium and vitamin D in palatable doses. Hyperthyroidism in the presence of insufficient calcium and phosphorus intake often produced osteoporosis. Severe cases of osteoporosis may lead to osteomalacia and spontaneous fractures. Gross deformities and dwarfism may result. These complications of hyperthyroidism can be treated best by feeding of adequate calcium, phosphorus and vitamin D. Muscular, joint and bone pains can

frequently be best controlled by calcium, phosphorus and vitamin D therapy. Thyroid crisis still occurs in spite of adequate iodization and often in a patient who is refractory to iodine. The authors feel that preoperative calcium, phosphorus and vitamin D are important in iodine refractory and the precrisis states, as well as in the prevention of thyroid crisis. Calcium, phosphorus and vitamin D should especially be administered to hyperthyroid patients who do not come to surgery early.

Massive Extrusions of Lumbar Intervertebral Disks.—VerBruggen thinks that insufficient stress has been placed on the serious complications which may occur when the ruptured intervertebral disk is inadequately treated. The extrusion of a large part of a disk may so compress the cauda equina as to cause weakness of one leg with disturbance of urinary function or even a transverse cauda equina lesion with paraplegia and incontinence of the bladder and rectum. Most of the patients with the cauda equina lesions seen by the author languished for days, weeks or months without a correct diagnosis being made. In all of the cases the lesion was at the lower lumbar vertebrae. The history is characteristically cog wheel in type, and the signs are those of acute compression of the cauda equina. The symptom complex varied from slight weakness of the legs below the knee with saddle hypesthesia to severe sphincter disturbances. Of 9 patients seen, 8 were operated on and 1 died before anything could be done. They represent the serious complication seen in 300 consecutive cases of typical herniated nucleus pulposus. All but 1 of the 9 cases presented a history of backache for years, and all but 2 a history of both backache and sciatica for years. A history of trauma was obtained in 3 cases. The bladder mechanism was not seriously involved in only 1 case. Weakness and hypesthesia were observed in varying degrees. The Lasègue sign was positive in all the cases in which it was tested. The deep reflexes in the ankle were affected in all the cases. The spine was tender on deep pressure in 6 of 8 cases. The intervertebral space was narrowed at the site of the herniation of the involved disk in 5 of 9 cases. Early diagnosis and operation are essential, but recovery may be slow and incomplete, even if the diagnosis is made early.

Transurethral Operation for Cord Bladder.—Thompson says that paralysis is so extensive in the vast majority of cases of cord injury that urination is impossible and remains so for many months. The distended bladder must be emptied. In the early phase of the paralysis the bladder of a few of these patients can be emptied by manual pressure applied in the suprapubic region. As time goes on these men usually find that the bladder cannot be completely emptied. The majority of paralyzed patients require drainage of the bladder through a catheter placed suprapubically through a stab wound, through a boutonniere incision in the perineal portion of the urethra or

through the penis. No matter where placed, the catheter must be irrigated regularly and changed at regular intervals. After a lapse of weeks or months, when the catheter is removed, some of these patients develop what is loosely called an automatic bladder. They void at irregular intervals but are usually incontinent to some degree; hence a urinal must be worn. If the indwelling catheter can be dispensed with, the patient's condition improves rapidly. Some patients will have spontaneous recovery of function. Patients who are unable to urinate after maximum nerve recovery has taken place can regain voluntary control of bladder function as the result of a properly performed transurethral resection of the vesical neck. It is important to remove a substantial amount of tissue. The resection of a few pieces from the posterior half of the vesical neck usually accomplishes nothing; tissue must be excised from the entire circumference of the outlet. Only in this way can the resistance of the retention mechanism be diminished sufficiently so that an increase of pressure within the abdomen, accomplished by straining, will squeeze the bladder dry. The most gratifying feature is that between urinations the patient has perfect control. Depending on fluid intake, four or more hours may elapse between urinations. If fluids are restricted in the evening, the patient can sleep all night. The author presents the histories of 5 patients. Voluntary bladder function was restored in all by transurethral resection of the hypertrophied internal sphincter. Prior to operation these patients had suffered from urinary retention and dribbling overflow incontinence. Since operation they have been able to void at will; they empty the bladder completely and have good control.

Acute Infectious Mononucleosis Simulating Acute Abdominal Emergency.—During the past six months aboard a heavy cruiser having an average complement of around 1,650 officers and men, Perisho and Sargent observed cases of acute infectious mononucleosis. In 4 of these, most or all of the signs and symptoms were confined to the abdomen and were of such character and severity as to simulate an acute surgical emergency. Two patients presented classic pictures of acute appendicitis, 1 of an acute diverticulitis (Meckel's) and 1 of a perforated peptic ulcer or ruptured spleen. The authors think that if the previous occurrence of typical cases of acute mononucleosis accompanied by sore throat and cervical adenitis had not made them "mononucleosis minded" these patients might have been subjected to unnecessary operation. It is probable that medical officers are too little aware of the fact that mononucleosis involving the mesenteric or retroperitoneal lymph nodes and spleen may simulate other abdominal diseases. The differential diagnosis depends principally on the differential leukocyte count.

Filariasis: Histopathologic Study.—Michael shows that histopathologic changes in the lymphangitis stage of filariasis may roughly be classified in two main divisions: (1) those presumably due to a generalized sensitivity caused by a distant worm focus with tissue changes occurring on an allergic basis and (2) those due to the presence of the worm in situ, resulting in local changes from absorption of worm products and, to a lesser degree, lymphatic obstruction. The author describes "fugitive swellings," skin tests with *Dirofilaria immitis* antigen, eosinophilic cell response and lesions in which worm segments, living worms, degenerated and calcified forms of microfilariae are found. The most important single diagnostic procedure, apart from the clinical history and physical examination, is the examination of a lymph node or lymphatic tissues for evidence of filariasis. All other laboratory procedures so far are inadequate, although skin testing with *Dirofilaria immitis* antigen is an aid. The problem, as judged from microscopic studies, is one of a foreign body engulfment and absorption of the parasite, resulting in the final production of scar tissue. Host resistance, augmented by action of the reticuloendothelial barrier, would seem to establish this lesion as being self limited in nature and ordinarily not productive of such sequelae as elephantiasis, lymph stasis and secondary infection. Not only will this infection not result in permanent damage to the vast majority of these patients but it will probably not become a public health problem in the future in the continental United States. The low percentage of microfilariae found in the peripheral blood and the absence of many of the optimal requirements for spread,

such as humidity and heavy rainfall, together with the low incidence of mosquitoes capable of serving as intermediate hosts, will serve to halt possible spread to the civilian population in the United States.

Sternal Puncture in Malaria.—Jacobson and Russell studied marrow smears. These smears were dried in the incubator at 37 C. for thirty minutes, were stained with Wright's stain for one minute, then immersed in Giemsa stain for thirty minutes and differentiated in distilled water, with observation of the color at frequent intervals under the microscope. The smears were dried and examined under the oil immersion objective. Each preparation was examined at least twenty minutes before being pronounced negative. The authors performed sternal puncture on 90 patients. They divide these patients into four groups. In the 13 patients of group 1 several blood smears, some obtained after the administration of epinephrine, had been negative prior to the bone marrow examination. Ten of these 13 patients showed the presence of vivax parasites in the bone marrow, an 1 the presence of falciparum parasites. In 2 of the 13 cases of this group the bone marrow was recorded as negative. The 49 patients of group 2 exhibited atypical symptoms or signs. In all blood smears were negative, but 10 of these 49 patients showed vivax parasites in the bone marrow. In the 15 patients of group 3 who had the clinical symptoms of malaria, ring forms had been observed in thick blood smears but the diagnosis of the species remained in doubt. Bone marrow examination permitted the identification of the species in all but 1 of these 15 cases. Group 4 comprised 13 patients, each of whom had from one to fifteen attacks of malaria. At the time of examination none of these patients had paroxysms of malaria. In all of them thick blood smears were negative. In 4 of these 13 cases the bone marrow revealed the presence of Plasmodium vivax. The remaining bone marrow examinations yielded negative results. The authors stress that in properly selected cases the bone marrow examination increases the chances of an accurate diagnosis of malaria.

Excision with Plastic Closures in Bedsores.—White and his associates show that sacral bedsores can be resected and closed by primary suture. This method is applicable to indolent ulcers of the type commonly seen after severe injuries to the spinal cord. In these cases adequate preliminary treatment must be given to correct anemia, reduced serum protein with edema secondary to malnutrition, and avitaminosis. Systemic and local chemotherapy should be used to clear up sepsis in the tissues surrounding the decubitus, in the bladder or in any

other focus. If the area does not fill in with granulation tissue and a satisfactory growth of epithelium fails to cover the surface, excision of the entire lesion and plastic closure is preferable to pinpoint or Thiersch grafting. This can be carried out without fear of serious sepsis if penicillin is injected intramuscularly during the period of healing. Five case histories are reviewed. In 2 of these there was primary healing; in the other 3 there was some separation of the edges of the flaps. Two of the latter required secondary plastic procedures of lesser extent. Sepsis was no problem. In place of an adherent avascular scar with a thin covering of epithelium, which generally results from pin point or Thiersch grafting, these patients all obtained full thickness skin with a healthy layer of subcutaneous fatty tissue as a covering of the pressure area over the sacrum. However, even after a pressure sore has been excised and covered with full thickness skin and subcutaneous tissue, it can break down again under the unfavorable circumstances which may arise in patients with transverse lesions of the spinal cord. In the after-care of these patients the same precautions must therefore be observed as in any case of anesthesia of the weight bearing areas.

Polyps of Cervix and Uterus.—Newgard and Morton report 228 cases of polyps of the cervix studied at the University of California Hospital in the decade between 1930 and 1940. Simple excision and/or cauterization was done in 96 cases, simple excision plus radium treatment in 77, cervical resection in 36 and total or vaginal hysterectomy in 18; the remaining 1 was only observed. Although all of these patients were treated in the hospital, not all patients with cervical mucous polyps require hospitalization. The main feature is to rule out cancer. A simple asymptomatic cervical polyp may be removed in an office, and its base cauterized, if one makes certain that no serious associated pathologic condition exists. If bleeding or even spotting is complained of the polyp cannot be considered as the definite cause, and a more thorough investigation usually with hospitalization is advisable. An uncomplicated cervical mucous polyp rarely gives symptoms. While many endometrial polyps are asymptomatic, discharge and bleeding of a spotty, intermittent type are more frequent here. Both types of polyps have to be strictly separated from other polypoid masses of the cervix or uterine cavity. Their structures resemble those of the cervical and uterine mucosa respectively. Secondary changes are frequent, the most important being the nonmalignant epidermization in cervical polyps and cancer in endometrial polyps. The term polyp is being used too loosely, which probably explains many of the so-called malignant cervical polyps reported in the past. While polypoid carcinoma of the cervix occurs and, very rarely, a true polyp may become malignant, these changes are usually evident on clinical examination and thus rarely cause confusion.

Chronic Intussusception in Children.—Garvie and Kemp report 3 cases, in 2 of which the condition was not suspected for a long time owing to the apparent absence of a palpable abdominal tumor, while in the third case the diagnosis was not made because the tumor did not persist. In the first case the intussusception first occurred at 2½ years of age. Spontaneous reduction must have ensued, for there were no symptoms for about two years. Three years ago the patient, a boy now 7 years of age, had an illness which was in the nature of a toxic reaction of the Henoch-Schönlein type, and there can be little doubt that the intussusception existed at that time, for thereafter he had attacks of pain about once a month. Despite the long standing illness, the boy's condition remained good and there was no wasting. The true diagnosis was never suspected because no abdominal tumor was palpated even during the paroxysms of pain. The x-ray examination gave conclusive evidence of intussusception. The common features in the histories of the 3 cases were repeated attacks characterized by the sudden onset of central abdominal pain. Any child who gives a suggestive history should be carefully examined, for owing to the difficulty in securing proper relaxation the tumor can be easily missed. X-ray studies should be made whether a tumor is palpable or not.

Ethyl Alcohol and Water for Sterilization of Skin.--

The measured volumes of alcohol and water were slightly stronger than their nominal strength expressed as percentages by volume. Archer found that for short exposure and on a dry surface the effective range of strengths of alcohol for the killing of nonsporing bacteria is between 90 and 50 per cent. Ninety-five per cent and above are partially ineffective, 100 per cent being especially so. The lower surface tension of stronger alcoholic mixtures suggests that the upper limits of this effective range may be preferable to the lower, though against this must be considered the more pronounced fixing effect of strong alcohol, which may cause the coagulation of an exudate and the consequent protection of living organisms within the coagulum so formed. Since the normal skin is more or less moist, the effective range of alcohol for use on it is somewhat different. The 100 per cent strength is commonly effective—at least on moister skins and under tropical conditions of temperature and humidity. The washing of the skin before the application of alcohol might exert a similar effect unless subsequent drying is thorough. The value of a low surface tension may well be of importance in increasing spread and penetration for skin sterilization. It is therefore considered that, as a general recommendation under all climatic conditions, 80 per cent of alcohol by volume is probably most suitable for skin sterilization, though this will not be more effective than any other nonpersistent agent for dealing with deep lying resident flora. Ether is quite ineffective as a sterilizing agent for the skin, since its effect is very slight on staphylococci and streptococci when applied to a surface—though it is effective against certain bacillary forms, both gram positive and gram negative.

Gastric Acidity and Urinary Hormone Content During Pregnancy.--Way observed in hyperemesis gravidarum a high incidence of diminution of gastric acidity in patients with hydatidiform mole. Since hydatidiform mole is associated with the presence in the urine of large amounts of anterior pituitary-like gonadotropic substance, it appeared that this factor might be responsible for the low secretion of acid in the gastric juice. Investigations were made on 63 patients who gave no history of gastric disorders. Twenty-two were between the thirty-fifth and fortieth weeks of pregnancy, 20 between the twentieth and twenty-ninth weeks and 21 between the eighth and sixteenth weeks. In addition 4 other patients were studied. One of these had a missed abortion and 1 a dead fetus at full term; 1 had a hydatidiform mole and one a chorionepithelioma. Evidence was obtained to show that in human pregnancy there appears to be some relation between the free and total acid in the gastric juice and the amounts of anterior pituitary-like gonadotropic substance secreted in the urine, and that it seems to be inversely proportional.

Action of Penicillin and Bacteriophage on Staphylococci.--

The organism used in the experiments was staphylococcus S3K. The bacteriophage was staphylococcus phage K producing a maximum titer of 10^8 with staphylococcus S3K. Its activity was measured by determining the last effective ten-fold serial dilution. The penicillin was the TRC 22 preparation of the sodium salt with a potency of 187 units per milligram. Degrees of lysis were assessed by comparison of turbidity with standards made from suspensions of formalized (1 per cent) staphylococcus cultures. Viable counts were made by the poured plate method. Hummelweil found that penicillin does not affect multiplication of staphylococcus phage K, acting on staphylococcus S3K, nor does it interfere with the lethal and lytic action of this phage. Staphylococcus phage K and penicillin together produce more rapid killing and lysis of staphylococcus S3K than either alone. Together they also effect rapid and complete sterilization, indicating that penicillin resistant organisms are killed by or through the agency of phage and vice versa. Lysis by bacteriophage as an "indicator" is capable of detecting concentrations of penicillin of 0.001 unit per cubic centimeter or less.

Prolonged Administration of Quinacrine.--Drew and Reid investigated 102 soldiers returning home from West Africa. Quinacrine had been ordered for all men as a malarial suppressive for the last four to eighteen months of their tour of duty. Malignant tertian (Plasmodium falciparum) malaria was the most important disease encountered. There were no cerebral or other grave forms of the disease, no complications like chronic splenomegaly and severe anemia. This favorable state of affairs is probably largely due to the antimalarial action of quinacrine. Nine men had slight hepatic and splenic enlargement, and 3 others had palpable spleens, but these conditions were symptomless. The hippuric acid synthesis test indicated temporary impairment in liver function in 9 men, 3 of whom had slight hepatic enlargement; but this was of doubtful significance since other liver function tests were all normal. Liver puncture biopsy of slightly enlarged livers showed that these had no deviation from the normal structure. There is no evidence that quinacrine in suppressive doses causes liver damage or other ill effects, but there is good reason to believe that the drug has prevented deaths from severe forms of malaria and from complications such as blackwater fever, and that its use can eliminate disability from chronic malaria.

Etiology of Hemolytic Disease of the Newborn.--

Walsh studied the relationship of blood group factors, especially the Rh factor, to the etiology of hemolytic disease of the newborn in 107 instances of the disease. The mother had Rh

negative blood and the child Rh positive blood in 92 per cent of the families investigated. An Rh agglutinin was found in the serum of 48 per cent of the mothers examined. The severity of the disease in the child was not related to the presence of the Rh agglutinin in the mother. The frequency and the severity of the disease generally increased with an increasing number of pregnancies, although some exceptions were noted. It is possible that extracorporeal Rh substance in the fetus may absorb some Rh agglutinin before it reaches the Rh positive erythrocytes. It was assumed that in 83 mothers with Rh negative blood the Rh factor was responsible for the hemolytic disease in the child, but there still remain the children with hemolytic disease who are born of mothers with Rh positive blood. The disease in seven such families investigated might be explained either by an ABO group incompatibility between the mother and the child or by the presence of an unknown agglutinin in the mother's serum. In five of the seven families there was an ABO group incompatibility, but in two families the mother and child belonged to the same ABO grouping. It may be pure coincidence that in the 2 latter cases the father had Rh negative blood. Unfortunately the possibility of the presence in the father's cells of an Hr or other agglutinogen could not be investigated. The relationship of the Rh factor to the etiology of repeated miscarriages, multiple stillbirths, and physiologic jaundice was investigated in a number of instances. The Rh factor was not the etiologic agent in the majority.

Sensitivity of Staphylococci to Penicillin.—North and Christie studied 128 strains of staphylococci of known biologic and metabolic characteristics, collected from various sources before the advent of penicillin treatment; all were tested for penicillin resistance. Thirty-one strains from hospital wards in which penicillin has been used extensively, particularly in local application to wounds, were also tested for resistance to penicillin. Their biologic and metabolic characteristics were compared with those of the 128 strains mentioned. Of the 128 strains from "nonpenicillin" sources, 123 were inhibited by one-eighth unit or less of penicillin per cubic centimeter, 2 were inhibited by one-fourth unit and 3 were inhibited by half a unit. The 5 strains showing slightly increased resistance were nonpathogenic. Of the 31 strains from patients in penicillin treatment wards 18 showed considerable resistance to the drug. All were pathogenic. The detection of such a large proportion of penicillin resistant strains in cultures received from penicillin treated lesions was unexpected. These strains showed no differences in common properties from normal strains. It is not known whether these resistant strains develop mainly from sensitive parent organisms in the same wound or are the result of cross infection either from carriers or air borne. From this preliminary study it has not been possible to determine to what extent these resistant strains have delayed the sterilization and healing of wounds.

- *Late Activation After Negative Tuberculin Tests. A. Courcoux, J. Gényvriat, M. Duret and A. C. Maclouf.—p. 229.
Angina Pectoris from Coronaritis in Young Persons. A. Jouve and R. Oddo.—p. 230.
Stricture of Ureter After Radium Therapy of Cancer of Cervix. L. Leger.—p. 231.

Late Activation After Negative Tuberculin Tests.—Courcoux and his associates believe that the late activation of tuberculin tests coincides most often with the acquisition of cutaneous sensitivity to tuberculin. This phenomenon is observed principally in subjects tested previously by the intradermal route. Late activation of old Mantoux tests is more frequent than that of old Pirquet tests. In one of their observations the authors were able to observe clearly the activation of tests performed more than twenty-four months before. This is the first observation in which so much time had elapsed between intradermal injection of tuberculin and its subsequent manifestation. In most of their observations the delayed activation caused very persistent reactions (several months). It is possible that the persistence of the induration may be linked to the amount of tuberculin that has been used. A mild and fleeting reaction may be elicited by a small dose, whereas a large dose may elicit a more intense and lasting reaction. In female

patients who have been tested many times, late activations may raise an esthetic problem. Young girls complained of the persistence of disagreeable indurations in the deltoid region, and nurses have asked that the tests be made on the thigh. Contrary to peremptory affirmations of certain observers, the authors do not think that retarded activation is the first sign of a severe primary infection.

*Significance of Hypocorticoadrenalism for Diagnosis and Therapy of Certain Disorders of Joint and Muscles. E. Lyon.—p. 219.
Fibrin Body: Report of Case with Unusual Feature. S. Schorr.—p. 224.
Treatment of Deafness with Benzylsuccinamate. Seelenfreund.—p. 228.

Hypocorticoadrenalism in Disorders of Joints and Muscles.—Lyon presents the case of a woman aged 56 in whom an existing hyperthyroidism had grown worse after the menopause. She also exhibited symptoms referable to insufficiency of the adrenal cortex: adynamia, gastrointestinal symptoms, arthropathy and muscular pain. She was given intramuscular injections of a concentrated extract of adrenal cortex, at first every day and later every second day. Soon after the institution of this treatment, pain and stiffness of the left shoulder joint subsided and other joint pain disappeared completely. Appetite improved, weight increased, and nausea, diarrhea and mental depression disappeared. Some of the symptoms reappeared when the injection of the cortical extract was discontinued, but they subsided again following the oral administration of a cortical extract. The author cites further evidence of the involvement of hypocorticoadrenalism in the pathogenesis of spondylarthritis-ankylopoietica. He suggests that the prolonged inflammatory infectious process in ankylosing spondylarthritis suggests a toxic depression of the adrenal cortex function as it is observed in diphtheria, scarlet fever and influenza. He also cites a case which indicates that hypocorticoadrenalism plays a part in the pathogenesis of dermatomyositis. Adrenal cortex extract therapy should be considered in the aforementioned conditions.

- Atypical Trigeminal Neuralgia Localized to Ophthalmic Division and Its Surgical Treatment. L. Preber.—p. 495.
Stellectomy by Lateral Scalenovertebral Approach. C. van Gelderen.—p. 519.
Experiments on Oxygen Therapy in Experimental Meteorism. A. Ringsted and K. Andersen.—p. 529.
*Primary Thrombosis of Axillary Vein: 7 Verified Cases of Thrombus Formation. E. Roelsen.—p. 547.
Femoral Fractures in Children: Some Views on Their Prognosis and Treatment. E. Hedberg.—p. 568.

Primary Thrombosis of Axillary Vein.—The disorder described by Roelsen is characterized by swelling of an upper extremity from the hand to the shoulder. The swelling does not pit like edema. The subcutaneous veins of the arm and the pectoral region are dilated and congested, and the hand and arm are somewhat cyanotic. There is a sensation of heaviness or slight pain in the arm, sometimes with reduction in muscular power. The history sometimes reveals excessive exertion with the involved arm. General symptoms, especially signs of infection, are absent. This condition, which is a manifestation of a more or less acute venous stasis, has been described under various terms, such as traumatic thrombosis of the axillary vein, exertion thrombosis or thrombophlebitis of the axillary (subclavian) vein and effort thrombosis. Recent investigations have revealed that the condition may develop in the absence of thrombosis. This has been confirmed by Roelsen in 3 of 7 cases under his observation. It is possible that in these cases thrombosis had existed previously (Veal's "post-thrombotic syndrome"). Surgical treatment in the form of venous resection is advisable only in protracted cases of stasis with repeated relapses. Venography may aggravate the stasis and edema and for this reason is inadvisable, particularly in the acute stage. Treatment with heparin was helpful in some cases. Immobilization is not advisable in thrombosis of the arm.

Book Notices

Acute Injuries of the Head. Their Diagnosis, Treatment, Complications and Sequels. By G. J. Howborthin, B.Sc. J.R.C.S. Surgeon in Charge, Department of Neurological Surgery, Newcastle General Hospital, Newcastle, England. With a foreword by Norman M. Dott, M.B. Ch.B. F.R.C.S. Neurological Surgeon, Royal Infirmary, Edinburgh, Scotland. Second edition. Cloth. Price \$8.70. Pp. 421 with 203 illustrations. Baltimore: William Wood & Company, 1945.

This splendid presentation of the subject of injuries to the head has been prepared for the information of the general practitioner and the medical student rather than the specialist. That it has served a useful purpose is evidenced by the fact that a second edition has been called for within three years after the appearance of the first. The material is presented clearly and in detail from the personal experience and point of view of the author. There is, however, little with which any one could disagree. The illustrations are for the most part excellent and serve their purpose well. A few, notably figures 33, 78 and 162, should be replaced by clearer photographs. Figure 62 erroneously gives the impression that a localized lesion in the superior temporal convolution would give rise to deafness and figure 63 that there are motor fibers in the anterior limb of the internal capsule. These, however, are all trivial matters which do not detract from the inherent value of the book. The practice of placing the references at the bottom of the page is a mistake. It is rare that the reader is in need of the full reference at the time he is reading the text, whereas having the references scattered throughout the book make them very difficult to find. The last chapters, on rehabilitation post-traumatic epilepsy and the final results of head injuries, will be found of interest to many readers. The other chapters dealing with the mechanism pathology, symptomatology and treatment of craniocerebral injuries will reward their reading by all who deal with these common injuries.

Hygiène contre venus. Guerre à la syphilis! Par Adrien Plouffe, docteur en médecine et en hygiène publique, directeur adjoint du Service de santé de Montréal. Préface d'une mère de famille. Papier. Price \$1.25. Pp. 221. Montréal: Les Éditions Immen, 1945.

This book by a French Canadian physician is a popular presentation of arguments and justification for instruction of young people with regard to the venereal diseases. It quotes religious authorities to substantiate the assertion that the maintenance of good health is a moral obligation. The author has evidently had in mind the need to make information available to comparatively simple and unsophisticated readers. Some of the principal facts with regard to syphilis and gonorrhea are given, and much attention is paid to the effects of syphilis in families and on children. The author strongly and repeatedly advocates premarital examinations. The book will probably be of considerable service to the type of reader whom the author had in mind.

Practical Anatomy of the Rabbit. An Elementary Laboratory Text-Book in Mammalian Anatomy. By the late B. A. Bensley, Ph.D. Seventh edition. Revised and edited by J. Horne Crook, Ph.D., Associate Professor of Comparative Anatomy and Zoology in the University of Toronto, Toronto. Paperback. Price \$1.70. Pp. 78 with 111 illustrations. Philadelphia: Blakiston Company, 1945.

The recurring editions (two since the death of the author) demonstrate the superior value and service of this book in the elementary teaching and study of mammalian anatomy. The present edition has a new section on the sense organs and an enlarged section on the structure of the liver. The illustrations, in both gross and microscopic anatomy, are excellent.

Your Eyes Have Told Me. By Louis H. Schwartz, M.D. Cloth. Price \$2.75. Pp. 208 with illustrations. New York: J. P. Dutton & Company, Inc., 1945.

The author presents his material for the layman and makes a rather dramatic effort to explain the various diseases and anomalies of the visual organ and its adnexa in simple language and by example. At times the language isn't quite simple

enough. In the preface he defines what he calls the four O's: optician, optometrist, oculist and ophthalmologist. The chapter subjects are interesting. The first, "Your Eyes Have Told Me," covers the relation of the eyes to general disease; "The Sins of the Fathers" is on what he calls hereditary Syphilis; "The Strange Case of Lady Nicotine and John Barleycorn" is about toxic amblyopia; "The Siamese Twins" deals with sympathetic ophthalmia; "The Lady With the Hard Eyes" is about glaucoma; "The Popeye Clinic" describes proptosis and "Monarch of All I Survey" presents the subject of visual fields. "Through the Looking Glass" and "Fundus Land" deal with the ophthalmoscope and fundus disease. On page 83 he states that contact glasses are placed against the cornea and held in place by the eyelids. The glass does not make contact with the cornea. It is held against the sclera by capillary attraction. On page 86 he states that "sympathetic ophthalmia" is more apt to follow a punctured wound in the cornea. A corneal wound alone never causes this disease. It follows injury to the uvea, regardless of whether the cornea or the sclera is the site of perforation. There are seven colored plates illustrating two normal and twelve pathologic conditions.

Enfermedades del corazón. Cirugía y embarazo. Por el profesor Dr. Ignacio Chavez, director del Instituto nacional de cardiología, México. D. F. Paper. Pp. 182 with 7 illustrations. México: D. F. Edición de la Colección nacional, 1945.

This book dealing with the problems of pregnancy and surgery in the cardiac patient, is based on a series of lectures delivered by the author in the Colegio nacional in Mexico City. The book is divided into six chapters. The first four chapters deal respectively with the hemodynamics of normal pregnancy, the clinical alterations observed in pregnancy, the clinical findings in pregnant women with heart disease and the considerations determining conception and the termination of pregnancy in the cardiac patient and the management of the cardiac woman who is pregnant. The last two chapters deal with the surgical risks involved in operating on the cardiac patient. The author has assembled from his large experience and a critical survey of the literature, including that in the English language a masterful presentation of the entire subject. It is a meritorious addition to current literature and clarifies the risks of pregnancy and surgery in the cardiac patient. It has succeeded in its aim of assembling the subject matter for use by the general practitioner. The specialist also will find its personal worth in this work.

Refraction of the Eye. By Alfred Cown, M.D., Professor of Ophthalmology, Graduate School of Medicine, University of Pennsylvania, Philadelphia. Second edition. Cloth. Price \$1.75. Pp. 278 with 184 illustrations. Philadelphia: Lea & Febiger, 1945.

This edition has been thoroughly revised and brought completely up to date in all scientific and technical aspects of the subject. The author employs the theory of ophthalmic optics in such a way that clinical aspects merge logically and in orderly sequence from their bases of scientific facts. In those portions of the text which deal with the theory of optics the method of detailed experiment, example and frequent repetition has been carried out. The reader is invited to make diagrams illustrating the theories involved by following the contents of the text. This is a material aid in learning such a difficult subject as physiologic optics, a subject which at its best presents a stumbling block both to beginners and to those advanced in ophthalmology. The first five chapters are devoted to an elucidation of refraction and reflection at plane and spherical surfaces. Five paragraphs are devoted to lenses. Eight chapters contain the basic elements necessary in obtaining a refraction of the eye. The section on refraction proper is well organized and complete and gives a brief outline of all the tests in vogue to date. The final chapter contains a complete description of contact glasses. The author is not overly enthusiastic concerning their use. The illustrations are exceptionally well planned and can be easily followed. This book should be a necessary addition to any ophthalmologist's library as it contains the basic fundamentals so necessary for a thorough understanding of the subject of refraction.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CLIMATE FOLLOWING RHEUMATIC FEVER

To the Editor:—A man aged 23 had in 1930, at the age of 8, an attack of rheumatic fever with a mitral regurgitation murmur but no joint involvement. This cleared up during the summer of 1931. In the winter of 1932 he had another attack, and this time both the mitral and aortic valves were involved. The mitral regurgitation cleared up shortly thereafter, but he still has a well compensated aortic regurgitation murmur. From the fall of 1932 to the present he has spent the winters in southern Arizona without trouble of any kind. He now plans to live in the vicinity of Cincinnati. What are the chances of a recurrence of rheumatic fever while living in a climate as typified by that of Cincinnati or of New York? What prophylactic medication and dosages are recommended to prevent further rheumatic attacks?

M.D., New York.

ANSWER:—While Ohio and New York both are areas with moderately high incidence rates for acute rheumatic fever, a patient of 23 has passed the age period of greatest susceptibility to this disease. The predisposition to further attacks of acute rheumatic fever which is observed following an initial attack gradually disappears, and in a patient like this, after an interval of fifteen years, this factor is probably not important. A mass of evidence has been developed to indicate that the prophylactic use of sulfadiazine in amounts of 1 Gm. daily will largely prevent the development of streptococcal disease due to sulfadiazine sensitive strains and, presumably for this reason, episodes of acute rheumatic fever. Sulfadiazine resistant strains of hemolytic streptococci are, however, appearing with increasing frequency and cannot be controlled by this procedure. While reactions to sulfadiazine in daily doses of 1 Gm., even when used for long periods, are infrequent, fatal complications occasionally do occur in the form of agranulocytosis or exfoliative dermatitis. The greatest incidence of streptococcal disease in Ohio and New York is ordinarily in the period of October 1 to June 1, and sulfadiazine prophylaxis, if used in these states, may be restricted to this portion of the year. However, it is doubtful that the probability of further episodes of acute rheumatic fever in the case under discussion is sufficient to warrant the use of this preventive procedure. Bacterial endocarditis perhaps constitutes a greater hazard than rheumatic fever for such a patient. Ideally it would be desirable to make a permanent home in an area of low incidence of streptococcal disease.

CEREBRAL SPASTIC PARALYSIS

To the Editor:—What is the value of curare in the treatment of a case of what seems to be spastic cerebral palsy in a girl of 5 years, delivered by forceps? She seems to be fairly bright mentally but is unable to walk. Athetosis and incoordination are pronounced. She is able to talk and has good health otherwise.

M.D., Nebraska.

ANSWER:—Curare has been used experimentally in cases of spastic cerebral paralysis but has not been used routinely because its use is not without danger. Curare, if given intelligently, can reduce or decrease muscle spasticity especially if followed by physical therapy, muscle education, hydrotherapy and occupational therapy. Unless a patient with spastic cerebral palsy can receive these helpful aids it is better not to use curare. If deformities are present a competent orthopedic surgeon should perform a tenotomy and any other procedures that are necessary. This should be followed by massage, hot water baths and galvanic stimulation. It is frequently surprising to see how well these patients do if they have normal intelligence.

SEBACEOUS CYST IN INFANT

To the Editor:—An 8 months old baby has a sebaceous cyst just below the bridge of the nose about the size of a small bean. It is increasing slowly in size and is disfiguring. It seems to be filled with sebaceous material. Would it be dangerous to incise and curet a cyst in this particular position?

M.D., Ontario.

ANSWER:—If the lesion is not infected, there is no reason why a sebaceous cyst like this should not be excised. It would probably be well to wait until the baby is a little older.

VITAMIN B COMPLEX IN DIABETES MELLITUS

To the Editor:—What is the opinion of competent authorities as to the efficacy of the supplemental treatment of diabetes mellitus with vitamin B complex? I would appreciate references to the medical literature pertaining to its use in this disease.

Major, M. C., A. U. S.

ANSWER:—The question, probably inspired by the report of Biskind and Schreier to the New York Academy of Medicine, that vitamin B complex used in treating diabetes would reduce or eliminate the use of insulin, involves two problems: (1) the possible effect of vitamin B complex in the treatment of uncomplicated diabetes mellitus; (2) the use of vitamin B complex for diabetic patients in the presence of complications which may require supplemental treatment with vitamins.

It is generally believed that in uncontrolled diabetes with glycosuria, polyuria and hyperglycemia the body may lack needed nutrients such as vitamins partly through loss by excretion and partly because the metabolic disturbance prevents their normal utilization. Therefore, while the diabetes is being brought under control by means of insulin and a diabetic diet, vitamin B complex may well be given, especially when diabetic coma has been present. Thiamine, riboflavin and nicotinic acid are considered to have a necessary place in the intermediary steps in carbohydrate metabolism (Soskin, in Wohl's *Dietotherapy*, 1945, p. 57).

Experiments such as those of Styron and his co-workers have been carried out in which diabetic rats and nondiabetic rats were studied during experimental thiamine deprivation and during the recovery when treatment with thiamine was given. No difference was observed in the length of time required by diabetic and nondiabetic rats to develop signs of deficiency. During the period of deprivation the glycosuria of the diabetic rats diminished, presumably because of the lowered food intake. Urinary sugar tended to reappear at the final stage of the deficiency during the time of polyneuritis. The carbohydrate tolerance tests showed little change until signs of pronounced deficiency appeared. Thus, lowered tolerance occurred when, by reason of the neuritis, muscular activity and power were lost. Actually when thiamine intake was greatly increased, carbohydrate tolerance seemed to improve. Vorhaus, Labbé and Mosonyi and their co-workers have reported improvement. Martin has described intensification of diabetes in depancreatized dogs on a vitamin B free diet, with great improvement in carbohydrate tolerance when thiamine and riboflavin were given. Other workers, notably Lepovsky, Wood and Evans and McIntyre and Burke, have recorded but little change in glucose tolerance either with deficiency or with excess of vitamin B. An extensive literature on thiamine is given by Williams and Spies. Wilder states that "at present the evidence of value in diabetes from therapeutic doses of the vitamin B complex, or any of its constituents, is conflicting but suggestive. The diabetic organism probably requires more vitamin B than easily is obtained in a mixed diet. When diets high in white flour are prescribed the danger of deficiency is increased, and with such diets it probably is wise to supplement the intake of the entire vitamin B complex by giving brewers' yeast. It has not been shown that doses of thiamine or riboflavin in excess of the amounts of these obtainable in well planned diets are therapeutically effective, except in cases in which the intake of these substances previously has been deficient." Certainly the therapeutic effect of giving vitamin B complex is not comparable in degree with that of a carefully balanced diet and insulin.

In cases of diabetes in which febrile complications, infections, pregnancy, lactation or achlorhydria have increased the need for or impaired the utilization of vitamins or when a definite neuropathy is present, vitamin B complex is generally useful. When a complicating vitamin deficiency exists, its relief may also be accompanied by improvement of the diabetes.

BLOOD GROUP SPECIFIC SUBSTANCES—"UNIVERSAL
DONOR" BLOOD

To the Editor:—What is the present status of the Witelsky substances A and B for converting all blood types into "universal donor" blood? Is it practical to use this material for banked blood in hospital blood banks? Is this material commercially available?

Walter J. Siebert, M.D., St. Louis.

ANSWER.—The use of solutions of the group substances A and B for conditioning group O blood to render it safe for use for patients of all blood groups is still in the experimental stage. In settling such a problem two points must be established: (1) the safety of the preparation and freedom from unpleasant reactions and (2) the efficacy of the preparation. Klendshoj and Witelsky (Transfusion of O Blood, Conditioned by the Addition of Blood Group Specific Substances, *THE JOURNAL*, Aug. 11, 1945, p. 1091) have established the first point beyond a reasonable doubt. Some of the earlier preparations of group substances had caused occasional unpleasant flushing of the skin, presumably because of the presence of residual animal proteins, but this difficulty seems to have been overcome in the more recent preparations. The second point is difficult to solve because dangerous reactions are extremely rare even when group O individuals are used as universal donors without any special precautions. In a series of 819 transfusions, Rosenthal and Vogel (Observations on Blood Transfusions from Universal Donors, in Mudd and Thalheimer's "Blood Substitutes and Blood Transfusion," Springfield, Ill., Charles C Thomas, 1942) encountered only a single hemolytic reaction that could be attributed to a high titer of isoagglutinins in the donor's serum, and this patient recovered from the reaction. Only a single completely proved case of a fatal hemolytic reaction due to the use of universal donor blood has been reported (Wiener, A. S., and Moloney, W. C.: Hemolytic Transfusion Reactions; Differential Diagnosis; "Dangerous Universal Donor" or Intragroup Incompatibility, *Am. J. Clin. Path.* 13:74 [Feb.] 1943); all the earlier reports must be discounted because they failed to take into account the possibility of reactions due to intragroup incompatibility with regard to the Rh factor. There has also been one report of a fatality from the use of unpooled plasma (Albertson, E. C.: Fatality Due to the Transfusion of Unpooled Plasma, *Am. J. Clin. Path.* 15:128 [April] 1945). The titers of the isoagglutinins in these 2 cases were so extremely high that probably they were not natural isoagglutinins but immune isoagglutinins. (The injection of pooled human plasma or therapeutic horse serum, both of which contain A and B group substances in solution, may stimulate the production of high titered immune anti-A and anti-B isoagglutinins.) If group O donors with a history of having received a plasma transfusion or a therapeutic serum injection are rejected as universal donors, this would remove a major source of danger from the use of universal donors (Wiener, A. S.; Soble, R., and Polivka, H.: Simple Method of Preparing Potent Blood Grouping Sera, *Proc. Soc. Exper. Biol. & Med.* 58:310 [April] 1945). With regard to the efficacy of the group substances in preventing dangerous reactions from the indiscriminate use of group O individuals as universal donors, there is no direct evidence supporting this claim. The claim is based entirely on the ability of the group substances to cause in vitro a definite reduction in titer of the isoagglutinins in normal group O plasma. Tests have not been made to determine whether a similar reduction in titer would occur with plasma containing high titered immune anti-A and anti-B isoagglutinins, such as are produced after plasma transfusions or injections of horse serum. The only way to settle this problem is take such a dangerous sample of group O plasma and divide it into two portions; inject half into a group A (or group B) patient unmodified; the remainder should be injected into a second patient of group A (or group B) after the addition of group substances.

The group substances are not yet commercially available. Group substances may be obtained for experimental use, however, from the Eli Lilly Company. In the meantime, the best procedure would be to weed out donors with dangerously high titers of isoagglutinins by testing a fixed dilution of their plasma, e. g. 1:50, with standard A₁ and B cells, or with the patient's cells. Those whose plasma does not react in this dilution are safe to use as universal donors. A conservative estimate would be that only one tenth of group O donors need be rejected as unsafe, and this simple procedure would obviate the need for expensive group substances. Incidentally, the injection of group O blood conditioned with group substances would cause a rise in titer of the isoagglutinins in the patient's serum, and it is not yet certain whether or not this might be harmful to a future infant, in case, for example, the patient is a woman of group O who later bears a group A child. CORONARY THROMBOSIS AND PREVENTIVE
INOCULATIONS

To the Editor:—An air cargo officer aged 38, 70½ inches (178 cm.) tall and weighing 145 pounds (66 Kg.), reported for physical examination and the inoculations necessary to leave the continental United States. On that occasion, at or about 2:15 p. m., he received 0.5 cc. of triple typhoid vaccine as prepared by the Army Medical School, 1 cc. of typhus vaccine (Cox) and 0.5 cc. of aluminum precipitated tetanus toxoid. Physical examination revealed the heart and blood vessels to be normal, the blood pressure 120/70; he was considered fit for arduous duty. Following the injections it is definitely stated that there was no collapse due to anaphylactic reaction or severe shock. On the evening of the same day symptoms characteristic of coronary occlusion developed. The patient was seen at about 8:30 p. m. by another physician, who reports that he complained of a severe pain in the region of his heart. The doctor was unable to make a diagnosis at this time but administered two hypodermics of morphine with scopolamine to relieve the pain. Another physician reported that examination of the heart with a stethoscope on the evening of the following day indicated a weak contraction and a friction rub over the lower heart area and that percussion revealed increased dullness to the right and left heart areas. The blood pressure at this examination was 105/80; the heart rate was not recorded. There was a rise in temperature, which continued for several days. Two days after the attack the leukocyte count was 15,000 and the blood pressure was 80/55. Electrocardiograms taken the first and third days subsequent to the incident revealing departure from normal predicate myocardial infarction of recent origin involving the anterior aspect of the ventricle. He was discharged from the hospital seven weeks later apparently in good condition, by ambulance. The final diagnosis was acute coronary thrombosis and myocardial infarction. Convalescence has been satisfactory. Was this patient's coronary thrombosis caused by the inoculations? If so, please discuss the mechanism by which this condition was produced.

Corroil E. Bingham, M.D., New York.

ANSWER.—It is probable that the attack of myocardial infarction secondary to acute coronary thrombosis had no definite relationship to the typhoid and tetanus inoculations that preceded it except an accidental one of coincidence in time. Considering the millions of persons of all ages who have received such inoculations, the precipitation of coronary thrombosis thereby should have become evident long ago. In years of experience with patients with coronary heart disease, infrequent coincidences of acute occlusion with one possible minor strain after another have been noted, but no direct relationship has been proved. Severe strain, as from trauma or strenuous effort, and prostration, such as may occur postoperatively, have, to be sure, seemed to favor the precipitation of an acute coronary thrombosis via a subintimal hemorrhage or rupture of a "cholesterol abscess," but in the absence of such severe strain no direct relationship can be deduced.

KÖHLER'S BONE DISEASE

To the Editor:—A white man aged 48 who was employed as a pin boy in a local bowling alley stated that about April 10, 1945 he was struck by a pin ball on the inner aspect of his left foot. This area became swollen, painful and ecchymotic. He was being treated for a contusion and then came to me on April 23, at which time no swelling or ecchymosis was present but there was exquisite tenderness over the region of the left scaphoid (tarsal) bone. The x-ray showed a small area of bone absorption involving the distal and medial portion of the tuberosity of the scaphoid bone and partially obliterating the bony trabeculations. I immobilized the foot in a cast, which I removed on May 23, at which time x-ray examination showed no material changes except that the cortical area appeared to be broken. Is this a cortical hemorrhage due to trauma which has caused an aseptic necrosis? What is advised as to treatment and prognosis?

M.D., Connecticut.

ANSWER.—The history of this patient suggests the possibility of Köhler's disease (osteochondritis) of the tarsal scaphoid. However, such conditions usually occur in younger persons. There is an excellent article by M. G. Karp on Köhler's disease of the tarsal scaphoid published in the *Journal of Bone and Joint Surgery* (19:84 [Jan.] 1937). Such a condition could be due to an acute bone atrophy of unknown etiology and may extend over many months but gradually responds to heat, massage and moderate activity. The subject of acute bone atrophy is well presented in an article by Thomas P. Noble and Emil D. W. Hauser published in the *Archives of Surgery* (12:75 [Jan.] 1926).

COMBINED IMMUNIZATION AGAINST WHOOPING
COUGH AND DIPHTHERIA—CORRECTION

The Query and Minor Note with this title published in *The Journal* April 21, 1945 stated that the combined diphtheria toxoid, alum precipitated, and pertussis vaccine produced by Eli Lilly and Company was made with "washed" bacteria. The firm writes that "washing" these organisms reduces antigenic potency and therefore this step is not employed in the preparation of "Perdipgen" nor is it used for the other vaccines of that company for active immunization against whooping cough.

PENICILLIN IN THE TREATMENT OF SUBACUTE BACTERIAL ENDOCARDITIS

A PRELIMINARY REPORT ON TWENTY CASES
TREATED OVER ONE YEAR AGO

HARRISON F. FLIPPIN, M.D.

ROBERT L. MAYOCK, M.D.

FRANKLIN D. MURPHY, M.D.

AND

CHARLES C. WOLFERTH, M.D.

WITH THE TECHNICAL ASSISTANCE OF MARJORIE WILEY
PHILADELPHIA

In June 1942 an intern at the Philadelphia General Hospital suffering with subacute bacterial endocarditis was treated unsuccessfully by us with penicillin. The total dosage was 225,000 units given over a period of seven days. Similar results with relatively small dosage were observed by others. Subsequent to these early reports, Loewe and his associates¹ and Dawson and Hobbly² were successful in the treatment of this disease by employing larger amounts of penicillin over longer periods of time. Following these encouraging results the Committee on Medical Research began a more extensive study of the use of penicillin in this disease, and this report represents a part of that investigation.

MATERIAL

This paper deals with the use of penicillin in the treatment of 20 cases³ of subacute bacterial endocarditis in which therapy was started over one year ago. Not included in this report are 2 moribund patients, 1 of whom died following a cerebral thrombosis and the other as a result of a massive pulmonary hemorrhage after receiving the drug for only three and five days respectively. A third patient, who was not accepted for treatment because the infecting organism was highly resistant to penicillin, is also omitted.

CLINICAL DATA

The relevant data are shown in the accompanying table. Seventeen of the patients were adults ranging in age from 18 to 63 years, and the remaining 3 were

From the Harrison Department of Surgical Research, University of Pennsylvania School of Medicine, and the Medical Clinic, Hospital of the University of Pennsylvania.

The work described in this paper was done under contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the University of Pennsylvania.

3. All of the patients were treated at the Hospital of the University of Pennsylvania except 1, who received treatment at the Philadelphia General Hospital.

children of 7, 10 and 12 respectively. Although it was impossible in many cases to determine the exact date of onset, the duration of disease at the time penicillin therapy was started has been approximated and found to vary from four to twenty-five weeks. Sixteen of the patients had rheumatic heart disease, 3 had congenital heart disease and the remaining 1 had arteriosclerotic heart disease. All of the patients in this study were of the white race.

INFECTING ORGANISM

Sensitivity of the infecting organism to penicillin was tested in all patients before treatment and was rechecked in those suffering relapses. The method used was similar to that described by Kolmer.⁴ Fifteen of the patients' organisms showed an original sensitivity to 0.025 unit and the remaining 5 cases were sensitive to 0.01 unit of penicillin. In patients that relapsed the organisms showed a definite loss of sensitivity to penicillin. Sensitivity studies were made with penicillin X in 1 case (15).⁵

TREATMENT

For the most part the method of administering penicillin, the dosage and the length of treatment in the present series were quite uniform. Patients were given, if possible, an initial course of 300,000 units of penicillin a day for fourteen days by continuous intravenous infusion. In cases with severe cardiac decompensation and in those in which suitable veins were not available the same amount of penicillin was administered intramuscularly. Patients in moderate cardiac failure tolerated the 3,000 cc. of intravenous fluid daily, if the solution was 5 per cent glucose in water and the dietary salt was kept low. As indicated in the table, the dosage and duration of therapy varied in patients requiring further treatment. No heparin was employed in the treatment of any of these cases.

RESULTS

Of the 20 patients included in this report, 16 showed a subsidence of infection; 12 of these are still alive and, with only 1 exception (18), are all well. The follow-up period in these cases varied from two to seventeen months. In this group of living patients 10 received only a single course (4,200,000 units over fourteen days) of penicillin, while the remaining 2 (15 and 18) suffered relapses and required additional treatment. One of these patients (15) received a total of over 86,000,000 units,⁶ administered intermittently during a period of almost twelve months, at the end of which

time the blood culture was still positive and the organism had become quite resistant to penicillin. This patient's organism was tested against penicillin X and found to be sensitive to 0.05 unit per cubic centimeter. The patient has been well for two months following the administration of 15,000,000 units of penicillin X over twenty-five days. The second patient (18) suffered three relapses, but since receiving 4,200,000 units intramuscularly over a period of twenty-one days she has been free from symptoms of the disease for over nine months. Within the past several weeks, however, she

patient (20) died suddenly with an acute coronary occlusion after being entirely free from symptoms and signs of infection for almost a year. These 4 patients all died outside the hospital and no postmortem studies were performed. Two patients (1 and 19) failed to respond to penicillin and died in the hospital. At post-mortem they were found to have active infection. Another patient (9) appeared to have responded to treatment only to die suddenly ten days later with what appeared to be an acute pulmonary embolism. The eighth patient who died (13) had two courses of

* Penicillin X.

has developed signs of early cardiac failure with no evidence of active infection.

Eight of the patients in this study are dead (40 per cent). In this subgroup 3 (2, 4 and 11) died as a result of cardiac failure occurring five, six and three months after treatment. As indicated in the table, 1 of these (11) suffered relapses after receiving three courses of 300,000 units per day for fourteen days but apparently had a clinical subsidence of infection after receiving 50,000 to 100,000 units per day intramuscularly for three months. This patient died three months after therapy was completed from congestive failure with no signs of recurrence of infection. A fourth

therapy, developed a secondary pseudomonas infection and died during the third course of penicillin. In this case thirty cultures were taken at appropriate intervals for six months after the second course and were negative, despite the presence of a continuous fever.

As already mentioned, there were 6 patients (1, 11, 13, 15, 18 and 19) who relapsed clinically and in each the blood culture was found positive. The time for recurrence of fever averaged twelve days, the longest being thirty days after treatment was finished. Blood cultures were always positive two to three days later, except in 1 case (13), in which the interval was six months. In this group of relapsed cases there was

observed a definite loss of sensitivity of the organism to penicillin. The culture in 1 case (19) was unfortunately lost. The most striking example of acquired resistance occurred in a man (patient 13) who received penicillin for almost a year. In this case the organism showed an original sensitivity to 0.025 unit, which increased to 0.75 unit. The same organism was tested against penicillin X and found to be sensitive to 0.05 unit.

ERADICATION OF POSSIBLE FOCI OF INFECTION

Since certain focal diseases may cause a recurrence of a case of subacute bacterial endocarditis, it is important that a careful search be made for possible foci of infection and their eradication effected if possible. Probably the most frequent focal diseases liberating bacteria into the circulating blood are tonsillitis, abscess of the teeth and otitis media. Because of the possibility of a transient bacteremia following tonsillectomy, dental extraction or the like we routinely administer sulfonamides or penicillin for several days before and after a surgical procedure. Furthermore, the patients are forewarned of the dangers of all dental manipulations and are advised to consult us about prophylactic measures if they contemplate having any dental work performed. Not included in this report is a patient with rheumatic heart disease who had a positive *Streptococcus viridans* blood stream infection and recovered following penicillin and the surgical removal of an arteriovenous aneurysm.

SUMMARY AND CONCLUSIONS

Twenty cases of subacute bacterial endocarditis were treated over one year ago with penicillin. Since there have recently appeared several excellent papers in which the salient features of this disease have been discussed, we will limit ourselves to several factors concerned with the management of these cases.

1. *Results of Penicillin Therapy.*—Of the 20 patients with subacute bacterial endocarditis, 16 had definite subsidence of their infection, 12 are still alive and with 1 exception are all well. Of the 8 who did not survive 4 were completely free of active infection and died as a result of heart disease. Three patients in this group failed to respond to therapy, and the eighth died soon after treatment was completed as a result of an acute pulmonary embolus.

2. *Establishment of Diagnosis by Positive Blood Cultures Before Starting Penicillin.*—Not infrequently a patient suffering with this disease is started on relatively small doses of penicillin before a positive blood culture is obtained. The dangers from this practice are threefold: 1. The organism may lose its sensitivity to penicillin. 2. The chances of obtaining a positive blood culture are lessened, despite the addition of penicillinase to the culture material. 3. The cardiac lesion itself undoubtedly progresses. Therefore it would seem best to withhold penicillin until a positive culture is obtained or, if the clinical diagnosis warrants, to administer adequate amounts of penicillin for the disease. In several cases, not included in this series, in which routine blood cultures were negative, we obtained positive results by employing anaerobic and arterial cultures.

3. *Adequate Penicillin Dosage.*—At this writing we are unable to make any conclusive statement regarding the amount or route of administration of penicillin for the treatment of this disease. As indicated, we employed 300,000 units a day for fourteen days as the initial course. This appeared adequate in 14 of the 20 cases.

However, in view of subsequent experience with 16 additional cases of the disease, not included in this report, we believe that all patients with subacute bacterial endocarditis should receive at least 500,000 units a day for at least five weeks.

We have used a continuous intravenous infusion of penicillin where possible, but we have no reason to believe that this method is any better than the intermittent intramuscular route. Sternal infusion of penicillin is practical for limited periods of time.

4. *Eradication of Possible Foci of Infection.*—As a precaution against reinfection, a careful search for possible foci of infection, such as infected teeth and tonsils, should be made, and, if surgical procedure is warranted, the patients are given full doses of sulfonamides or, preferably, penicillin before and after operation.

5. *Penicillin X.*—In a case in which the infecting organism had become highly resistant to penicillin, we employed penicillin X with apparent success.

RHEUMATOID SPONDYLITIS

A STUDY OF ONE HUNDRED CASES, WITH SPECIAL REFERENCE TO DIAGNOSTIC CRITERIA

MAJOR EDWARD W. BOLAND

AND

MAJOR ARTHUR J. PRESENT

MEDICAL CORPS, ARMY OF THE UNITED STATES

Although rheumatoid spondylitis is one of the most crippling of the chronic diseases affecting the spine, it has evoked but little interest except among rheumatologists and orthopedists. Contrary to general belief, the disease is a fairly common cause of chronic back complaints in young men. Often the diagnosis is not established for several years after the onset, and the early symptoms are frequently mislabeled as lumbago, fibrositis or muscular rheumatism, chronic low back strain, kidney disease or idiopathic sciatica. If physicians are alert, however, to the characteristic clinical and roentgenographic features of the disease, diagnosis should not be difficult even in the early stage.

A surprisingly large number of soldiers with chronic back disability suffer from rheumatoid spondylitis; 18 per cent of patients with chronic back complaints admitted to an army general hospital were found to have this disease. The majority of these were early or relatively early cases. Such a high incidence among young men makes an appreciation of the diagnostic features, especially the early manifestations, important to physicians.

NATURE OF THE DISEASE

Rheumatoid spondylitis is a chronic progressive disease of the spine the fundamental lesions of which occur in the diarthrodial or synovial joints; that is, the sacroiliac, small posterior intervertebral (joints of the articulating processes, apophyseal or facet joints) and costovertebral articulations. The intervertebral disks are not affected, nor are the vertebral bodies except for secondary demineralization. Calcific and later osseous changes develop in the paravertebral ligaments and, when pronounced, characterize the classic roentgenographic picture of a "bamboo spine"; but ligamentous

From the Medical and Radiologic Services, Hoff General Hospital, Santa Barbara, Calif.

Major Boland is now stationed at the Army and Navy General Hospital, Hot Springs National Park, Arkansas.

calcification is not an essential feature. The pathologic process usually, but not invariably, begins in the sacroiliac joints and then may spread upward to involve progressively the synovial joints of the lumbar, thoracic and cervical regions. With continued progression, movement of the spine decreases, a thoracic stoop develops, the chest becomes relatively fixed in expiration and the neck may protrude, resulting in the clinical picture of a "poker spine." The process may become arrested at any point, however, and such extensive deformity need not always eventuate.

Whether the disease is but an expression of rheumatoid arthritis as it involves the spine or a separate pathologic entity remains disputed. The contention that it is an independent disease is based on the following facts: (1) The prominent ligamentous calcification and ossification, seen in the later stages of spondylitis, is not a feature of rheumatoid arthritis involving peripheral joints; (2) the sex incidence in spondylitis favors males, while peripheral rheumatoid spondylitis is more common in females; (3) chrysotherapy may produce remissions in some cases of peripheral rheumatoid arthritis but is ineffective in spondylitis; (4) roentgen therapy may be of value in spondylitis but does not alter the course of rheumatoid arthritis affecting the peripheral joints. Those who believe that the disease is but rheumatoid arthritis of the spine point out that (1) typical rheumatoid arthritis involving peripheral joints frequently coexists, (2) the sedimentation rate is elevated and (3) the pathologic changes in the diarthrodial joints of the spine during active phases resemble those found in rheumatoid arthritis.¹ We believe, as do many other American investigators,² that the evidence favors the concept that the disease is a variant of rheumatoid arthritis.

A myriad of synonyms for rheumatoid spondylitis have appeared in the literature, based on (1) concepts of the nature of the process, (2) variations in location of involvement and (3) whether the disease was acute or chronic, transient or progressive. Such confusing terms as rhizomelic spondylitis, Marie Strümpell's disease, spondylitis ossificans ligamentosa of Knaggs, von Bechterew's syndrome, ankylosing spondylitis, adolescent or juvenile spondylitis, spondylitis ankylopoietica and spondylarthritis have been offered. The lack of uniform terminology has fostered confusion regarding the disease among physicians.

MATERIAL AND STUDY

One hundred soldiers with rheumatoid spondylitis were selected for study. No case was included in which the diagnosis was equivocal; roentgenographic findings in the sacroiliac joints, characteristic of the disease, were present in each case. Clinical and x-ray investigations and their correlation were made while the patients were under observation in the hospital.

The cases were classified on the basis of severity as determined by (1) the rapidity of clinical progression, (2) the degree of disability as manifested by the presenting symptoms and physical findings, (3) the amount of constitutional reaction, the height of the

sedimentation rate and the degree of anemia and (4) the character of the roentgenographic changes. Such classification is more practical than a division based on roentgenographic findings alone, as has been suggested by some.³ Roentgenographic manifestations usually fail to reveal the actual extension of the process as noted clinically and, although often helpful in gauging activity, they do not accurately reflect the clinical course of the disease. Of the 100 cases studied 40 were classified as mild, 50 as moderate and 10 as severe.

INCIDENCE, AGE AND SEX

Of patients with complaints referable to the musculoskeletal system due to a variety of causes, including arthritis, admitted to the medical service, 7.5 per cent were found to have rheumatoid spondylitis. One patient with spondylitis was admitted for every 3 with rheumatoid arthritis involving peripheral joints alone. These figures are in sharp contrast to those based on civilian practice. For example, 26 cases among 1,179 patients with arthritis were recognized by Hare,⁴ an incidence of 1.7 per cent. The ratio of spondylitis to peripheral rheumatoid arthritis has been reported as 1:11,⁵ 1:13⁶ and 1:19.⁴ The relatively high incidence of the disease in soldiers may be explained by (1) the preponderance of males in the army of an age group for which the disease has a predilection and (2) the influence of physical activity and adverse living conditions incident to military service in bringing to light mild and early cases. It is not probable that military life in itself is a causative factor. Of interest is the fact that German writers noted an increased frequency of the disease among soldiers in World War I.⁷

All of the patients studied were males. Rheumatoid spondylitis is chiefly confined to the male sex, the ratio of males to females affected being approximately 20:1.⁸

Ninety-two per cent of our cases were observed during the third and fourth decades of life. The onset of symptoms occurred between the ages of 20 and 29 years in 69 patients, between the ages of 30 and 39 years in 16 and between the ages of 16 and 19 years in 15. These figures are consistent with the findings of others.⁹

ASSOCIATED PERIPHERAL RHEUMATOID ARTHRITIS

Typical rheumatoid arthritis of the peripheral joints coexisted in 18 of the 100 cases; in 5 others a past history of joint disability accompanied by swelling was elicited, which from description suggested rheumatoid arthritis. In 8 of the 18 cases the peripheral joints were affected first, in 6 the first symptoms were in the back, and in 4 the involvement was more or less simultaneous. The hips were involved in 3 patients, the knees in 10, the ankles in 4, the metatarsophalangeal joints in 10, the proximal interphalangeal joints of the toes in 2, the shoulders in 3, the elbows in 3, the wrists in 5, the metacarpophalangeal joints in 6 and the proximal interphalangeal joints of the fingers in 4. These

Oppenheimer, A.: Diseases of Apophysal (Intervertebral) Articulations, *J. Bone & Joint Surg.* 20:285-313, 1938.

findings do not support the opinion that small peripheral joints are rarely involved.¹⁰ Although the clinical and roentgenographic manifestations in the spine may be identical, some authors would classify those cases with associated small joint involvement as "rheumatoid spondylitis" and those without peripheral arthritis as "rhizomelic spondylitis." Such a division does not seem to be justified. The frequent association of rheumatoid arthritis of the extremities with the spinal changes of so-called rhizomelic spondylitis strongly supports the contention that the latter condition is rheumatoid arthritis of the spine.

PRECIPITATING FACTORS

Such possible precipitating factors as trauma, exposure, focal and other infections, psychic strain, gonorrhea and preceding subnormal health were studied in detail in each case. In 80 per cent no possible immediate precipitating cause could be elicited, and in the remaining 20 per cent no constant factor could be found. Eight patients dated their first symptoms to minor back trauma, but it is probable that in these injury merely brought an existing condition to light symptomatically. Four others had previously sustained incapacitating back injuries which were temporally unrelated to the onset of spondylitis. In 5 of the 100 cases acute gonorrheal urethritis was related to the onset of back symptoms, and in 8 others an unrelated past history of gonorrhea was elicited. The incidence of gonorrheal infection was approximately the same as that noted in patients with peripheral rheumatoid arthritis. The opinion expressed by some that gonorrhea may serve as an etiologic agent was not supported by the present study. Gonorrhea probably serves as a "trigger" mechanism (as may other infections) in some cases as it may in peripheral rheumatoid arthritis. In 1 instance a nonspecific urinary infection immediately preceded the first back symptoms. There was no definite relationship of dental, tonsillar or paranasal sinus foci of infection to the onset of spondylitis in any patient.

SO-CALLED PRESpondylitic STAGE

Each patient was questioned in detail in an attempt to elicit and to evaluate peripheral muscle and joint complaints occurring prior to the onset of spinal symptoms. Scott¹² and others¹³ described a "prespondylitic stage" characterized by wandering fleeting pains in the shoulders, arms, ribs and legs during which the sacroiliac joints presumably were silently involved. They maintained that spinal symptoms did not develop until bony ankylosis of the sacroiliac articulations was nearly complete. The present study yielded no evidence to justify the concept of a so-called prespondylitic stage. In 10 patients we were able to elicit a history of migratory peripheral joint and muscle complaints with or without stiffness. Such complaints usually were not impressive, or they had characteristics which suggested the syndrome of "fibrositis." Except for those patients with, or a past history of, rheumatoid arthritis involving the peripheral joints the first definite rheumatic complaints were almost always located in the back.

CLINICAL PICTURE

Mode of Onset.—In 82 of 100 cases the onset was insidious. Almost invariably the first complaints were referred to the lower part of the back and in 84 per cent consisted of episodes of aching and stiffness, transient back pain or sciatica.

Episodes of aching and stiffness, lasting a few days at a time and then subsiding completely or almost completely, were the most frequent initial complaints. Occasionally these symptoms were persistent from the onset. Qualitatively the aching and stiffness presented characteristics of the syndrome of "fibrositis," that is, being most pronounced in the morning on arising, accentuated by physical inactivity and ameliorated by mild exercise, made worse by damp weather and temporarily relieved by local heat and by acetylsalicylic acid. Although the intensity varied, the symptoms were mild in most cases; but, in a few, disabling attacks often described as "lumbago" occurred. Later the aching and stiffness tended to be more persistent and to lose the typical characteristics of fibrositis.

Less frequently the first symptoms consisted of transient sharp pains or "catches" in the buttocks and hips and in the lumbosacral, sacral or lumbar regions. Often these were precipitated by twisting, jolting, bending, lifting, coughing or sneezing but at times occurred spontaneously. Later, if not at the onset, aching and stiffness accompanied such pain. As the disease progressed, pain tended to become a constant dull discomfort, often described as a "deep ache," a "tired feeling" or a "soreness" and aggravated by activity entailing weight bearing or movement of the back. Not infrequently the discomfort was pronounced at night.

In 8 patients the first symptom was sciatic pain. In 6 it was intermittent and in 4 it alternated from one side to the other. The sciatica associated with rheumatoid spondylitis is rarely severe, is seldom accompanied by neurologic findings and frequently alternates from side to side.

Miscellaneous types of onset were recorded in 16 cases. A vague "tired aching" in the lower part of the back, especially following walking or standing, was noted by 4. Thoracic girdle pains constituted the initial complaint in 3. Pain in the right costovertebral angle radiating into the inguinal region, simulating renal colic, was described by 1. Three patients recalled progressive limitation of back motion without actual discomfort. One patient, bedridden with severe peripheral rheumatoid arthritis, had noted only vague, ill defined backache. Three others, with long standing spondylitis, were unable to recall the initial symptoms.

Symptoms and Findings.—Although the overall pattern of rheumatoid spondylitis is fairly characteristic, the clinical picture at the time of examination is variable. The symptoms and findings are dependent on (1) the severity, rate of progression and duration of the disease, (2) the extent of spinal involvement and (3) the activity of the process at individual levels of the spine. The disease may be mild, moderate or severe; it may be localized to the sacroiliac joints or at the other extreme may involve the synovial joints of the entire spine; it may be semidormant and silent in one area while active and symptomatic in another. The severity of symptoms and the extent of the physical findings are dependent on such qualifying factors.

While the disease may begin at any level in the spine, it begins in the sacroiliac joints in the vast majority of instances. The process may subside temporarily or may terminate permanently at any point, but the ten-

dency is toward a gradual and relentless spread to higher levels. Hence in most instances the sacroiliac joints are involved at the time of examination, and, as a rule, the lumbar spine is affected before symptoms appear in the thoracic spine. Occasionally, however,

Fig. 1.—Contour of the normal back with the trunk moderately flexed. The contour may be normal when involvement is restricted to the sacroiliac joints.

Fig. 2.—Moderately advanced rheumatoid spondylitis, showing limitation of motion and straightening of lumbar spine. Paravertebral muscle spasm is present in the lower thoracic and upper lumbar regions. Note the muscle atrophy in the lumbosacral area ("ironed out" appearance).

the disease apparently by-passes one or even two segments and consequently different combinations of symptoms and findings may be encountered. As it would

not be practical to describe all possible variations, an enumeration of the features resulting from involvement in individual segments may be useful.

Sacroiliac Involvement.—When these joints alone are the sites of active rheumatoid arthritis, the symptoms consist of aching, stiffness and pain in the lower part of the back which qualitatively have already been described. Sciatica occurs in approximately 10 per cent of instances. Tenderness over one or both sacroiliac joints may be elicited on percussion or deep palpation in over 50 per cent of patients with early changes; as ankylosis develops, tenderness (and pain) disappear. Various orthopedic maneuvers which produce sacroiliac joint movement may cause local pain. Mild lumbar paravertebral muscle spasm without restriction of lumbar motion is frequent; pronounced muscle spasm usually indicates lumbar apophysial joint involvement.

In very mild cases or when the sacroiliac joints are ankylosed (and unaccompanied by higher involvement), physical signs may be entirely absent.

Lumbar Involvement.—The lumbar segment is rarely involved alone, and almost invariably the disease has extended from the sacroiliac joints. Pain, aching and stiffness, as already noted, remain the dominant symptoms but are not of great localizing value. Sciatica is not uncommon. Among the signs which signify involvement of the lumbar spine are (1) limitation of motion of the lumbar spine, (2) paravertebral muscle spasm, (3) straightening of the normal lumbar lordosis, (4) tenderness

(constant) to percussion and deep palpation over or just lateral to the lumbar spinous processes, (5) pain in the lumbar spine on flexion (anterior and lateral) and extension, (6) muscle atrophy, especially in the lower portion of the lumbar segment, which when combined with straightening gives the lower back an "ironed out" appearance (figs. 1 and 2), and (7) anterior stoop (usually associated with thoracic involvement).

Thoracic Involvement.—When the thoracic segment is affected the findings result from involvement of the thoracic posterior intervertebral joints, the costovertebral joints and the thoracic nerve roots. These include (1) tenderness (constant) on percussion and deep palpation over or just lateral to the thoracic spinous processes, (2) muscle spasm and later muscle atrophy,

Fig. 3.—Characteristic posture in spondylitis involving entire spine. Note the lumbodorsal stoop, the flattened anterior chest and the protruded neck. Both hips are involved, with flexion deformity on the left.

(3) limitation of motion of the thoracic spine, (4) girdle pains, (5) diminished chest expansion with reduction of vital capacity, (6) flattened anterior chest (expiratory position, fig. 3), (7) chest pain on forced inspiration and (8) thoracic kyphosis (thoracolumbar stoop).

Cervical Involvement.—With involvement of this segment the features presented are (1) tenderness (constant) on percussion and palpation over the posterior neck, (2) pain (constant) on forced motion of the cervical spine, (3) restricted motion of the neck, (4) spasm and later atrophy of the cervical muscles, (5) protruded position of the neck and (6) cervical radicular pain (rare).

Constitutional Reaction.—General constitutional symptoms such as weakness, fatigue, anorexia, weight loss and low grade fever are rarely prominent features of spondylitis unless the disease is severe or unless peripheral joints are concomitantly involved. Such reaction, as a rule, parallels the height of the sedimentation rate. Mild cases may be accompanied by minimal or no constitutional symptoms, and many patients may

paraspinal ligaments. Except for secondary demineralization the vertebral bodies are not affected. The intervertebral disks remain intact.

X-ray alterations of the synovial joints result from destruction of articular cartilage and changes in the subchondral bone. When the pathologic process is

Fig. 4.—Normal sacroiliac joints. Note the clear joint spaces and the sharp borders.

pursue useful occupations for years without appreciable alteration in general health.

Laboratory Findings.—The erythrocyte sedimentation rate serves as the most consistent laboratory gage of activity in spondylitis, just as it does in peripheral rheumatoid arthritis. It was elevated in 78 of 100 cases. The usual range was between 20 and 60 mm. in one hour (modified Westergren, normal under 20 mm. in one hour for males), the most rapid being 112 mm. in one hour. In several patients with mild but active disease the sedimentation rate was repeatedly within normal limits. Others have observed that when the disease is mild with insidious onset and slow progression the sedimentation rate may be normal.¹⁴ Moderate hypochromic anemia was present in 28 patients.

ROENTGENOGRAPHIC FEATURES

The roentgenographic features of rheumatoid spondylitis are quite characteristic. In general they are reflections of those pathologic changes which develop in the sacroiliac and apophysial articulations and in the

Fig. 5.—Moderately advanced mild rheumatoid spondylitis. The sacroiliac joints are blurred and the margins are indistinct. Note the juxta-articular increase in bone density in the ilium and sacrum.

restricted to the synovial membrane, the x-ray appearances are normal. Synovitis may exist for months or even for two to three years before cartilage or bone is sufficiently modified to be recorded by roentgenograms. Hence symptoms of the disease may be present long before positive x-ray diagnosis is possible. Similarly, in patients with ascending disease there is an appreciable lag between the development of physical findings and x-ray alterations.

Sacroiliac Joint Changes.—Significant alterations in the sacroiliac joints existed in each of the 100 patients; the involvement was bilateral in 96. Although rheumatoid spondylitis may be suspected on clinical grounds alone, we have hesitated to make an unequivocal diagnosis when the sacroiliac joints have appeared normal.

Fig. 6.—Moderately advanced rheumatoid spondylitis of moderate severity. The sacroiliac joints are indistinct and mottled. Note the serrated sacroiliac joint borders and the juxta-articular sclerosis.

Abnormalities in these joints almost invariably are more definite, more advanced and more diagnostically reliable than are alterations elsewhere in the spine.

The normal sacroiliac joint in young men is clear and its borders are sharply outlined. The earliest changes in spondylitis consist in a blurring or "ground"

¹⁴ Forrester, J.: Importance of Sacroiliac Changes in the Early Diagnosis of Ankylosing Spondylitis; Marie Strümpell Disease. *Radiology* 33: 280-402, 1939. Golding.

glass appearance. The margins are no longer distinct or they may appear broken. The juxta-articular portion of the ilium and frequently the sacrum may demonstrate increased density, spotty osteoporosis or both.

Subsequent changes are at least partially dependent on the severity and the duration of the disease. When the process is mild, juxta-articular sclerosis is more prominent than spotty rarefaction, and mottling of the joint space is minimal or absent (figs. 4 and 5). Rather, the joint space tends to become less distinct and more narrowed until ankylosis finally develops. When the disease is more severe the joint space appears widened and irregularly mottled (fig. 6). The lower portion may assume a "honey combed" appearance, and later extensive "rosary" formation or scalloping with cystic caries of the margins may be found. Complete dissolution with fragmentation and disappearance of sacroiliac contours is an occasional extreme finding. Concomitantly, varying degrees of sclerosis and localized rarefaction in the adjacent ileum and sacrum occur. In general the degree of spotty juxta-articular bone atrophy and joint mottling seem to vary directly with the activity of the disease. When ankylosis begins to develop, subchondral sclerosis becomes more apparent, mottling is less pronounced and the joint space gradually becomes narrowed. When synostosis is established, the areas of increased density fade. Eventually there is continuity between the sacrum and ilium with little or no trace of the joint (fig. 7).

Posterior Intervertebral (Apophysial) Joint Changes.—By no means were changes in the apophysial joints as definite or as constant as those in the sacroiliac articulations. Even with the use of special technics, detailed studies often yielded disappointing results. In no instance in this series were there typical findings in the apophysial joints without accompanying evidence of sacroiliitis. When apophysial changes were found usually only a few scattered joints were abnormal while intervening ones appeared normal. Presumably the pathologic process in the interposed normal appearing articulations had not produced sufficient cartilaginous or bony change to be registered roentgenographically.

Fig. 7—The sacroiliac joints are ankylosed. Note the demineralization, which is a common finding when fusion is complete.

Qualitatively, the apophysial alterations were similar to those found in the sacroiliac articulations. Early there were haziness and indistinct outlining of the joint. Stippled decalcification and/or sclerosis of the articular process was often evident. Later, in more severe cases, erosion, scalloping or perhaps a single cystic rarefaction of the facet surface was a typical finding. All degrees of destruction have been noted in the same

spine with completely normal intervening joints at some levels. As in the sacroiliac joints, the final event consisted of bony ankylosis, but even in this phase not all the joints of an involved segment were fused.

Paraspinal Ligament Changes.—Calcification and ossification of the paravertebral ligaments do not develop until the disease is moderately advanced. The anterior,

Fig. 8—Extensive ligamentous calcification producing the terminal picture of a "bamboo spine." Note the secondary demineralization of the vertebral bodies. The intervertebral disc spaces are normal in height and contour.

lateral and posterior longitudinal ligaments and the ligamenta flava are the usual sites of calcific changes. Calcification most often begins in the lower thoracic and upper lumbar portions of the spine. All degrees of calcification and ossification may be found, ranging from fine penciled lines in the anterior spinal ligament to extensive "bambooning" (fig. 8). In a few exceptional cases definite ossification of the ligaments was observed in the lower thoracic and upper lumbar spine when only minimal and early changes were present in the sacroiliac articulations. In these instances the disease probably began in the apophysial joints of the thoracolumbar spine rather than the sacroiliac articulations.

CLINICAL COURSE

The course of rheumatoid spondylitis is extremely variable and to a large degree is dependent on the severity of the disease. Mild cases, which are characterized by insidious onset, little or no elevation of sedimentation rate, minimal or no constitutional symptoms and x-ray changes showing predominant juxta-articular sclerosis rather than spotty osteoporosis or joint mottling, tend to run a relatively benign course. Symptoms may be mild and not incapacitating for years. Progression of the disease is gradual but none the less relentless, and the stage of "poker back" deformity may not be reached for fifteen to twenty-five years. As has already been pointed out, the disease may, however, temporarily or permanently subside at any point. For example, it may terminate before it has extended beyond

the sacroiliac joints, and the only residue of the disease may be the x-ray "ashes" of completely ankylosed sacroiliac joints. To be kept in mind is the fact that an apparently "burned out" process may become reactivated at any time.

In moderately severe cases back disability is usually of sufficient severity for the patient to seek medical aid. Progression is more rapid, the sedimentation rate is almost invariably elevated and the roentgenograms reveal changes which signify a higher degree of disease activity. Pronounced restriction of back motion, diminished chest expansion, lumbodorsal stoop and neck involvement may be evident within five to ten years in those cases which show continued extension. The activity of the disease may fluctuate, however, and there may be alternating periods of temporary improvement and exacerbation.

Severe instances of the disease usually demonstrate pronounced back disability, definite constitutional reaction and rapid progression. We have observed extreme deformity with complete rigidity of the spine in all segments ten months after the first onset of symptoms. In some, spondylitis is merely a part of a severe generalized rheumatoid arthritis in which the peripheral joints share equally in the involvement.

DIAGNOSIS

When rheumatoid spondylitis has advanced sufficiently to produce characteristic physical and roentgenographic signs, little difficulty should be encountered in diagnosis. Such clinical features as progressive limitation of spinal motion, pronounced muscle spasm, straightening of the normal lumbar lordosis, muscle atrophy, lumbodorsal stoop, diminished chest excursion, flattening of the anterior thorax or protrusion of the neck, when observed in almost any combination, should serve as adequate clues. Such roentgenographic findings as bilateral sacroiliitis, apophyseal joint changes and ~~anterior~~ ^{posterior} lumbar spine, perhaps accompanied by calcification and ossification, should confirm the diagnosis. Other features, such as an elevated sedimentation rate, constitutional symptoms or associated peripheral rheumatoid arthritis, serve as additional evidence. The extreme case with poker back deformity can be readily spotted on the street corner.

Early cases may be easily missed, however, unless the possibility of the disease is considered in every patient with chronic back complaints. The following points, axiomatically summarized, may be helpful in recognizing early rheumatoid spondylitis:

1. Suspect rheumatoid spondylitis when a young man complains of chronic recurrent or persistent low back aching and stiffness, with or without catching pains, especially if the sedimentation rate is elevated.

2. Suspect rheumatoid spondylitis in the young man who complains of such vague symptoms as a "tired feeling" in the lower part of the back on standing and walking, persistent low back soreness, silent restriction of back motion, or indefinite sharp pains in the buttocks, hips or lower part of the back, especially if accompanied by an elevated sedimentation rate or general constitutional symptoms.

3. Suspect rheumatoid spondylitis in all cases of sciatica in young men, particularly if recurrent or alternating from side to side or associated with aching and stiffness of the lower back.

4. Suspect rheumatoid spondylitis in patients with thoracic girdle pains, especially if accompanied by symptoms in the lower part of the back.

5. Suspect rheumatoid spondylitis when persistent back symptoms develop in a patient with peripheral rheumatoid arthritis.

6. In the absence of roentgenographic evidence of sacroiliac involvement an unequivocal diagnosis of rheumatoid spondylitis should not be made unless characteristic changes are present in the apophyseal joints.

7. Remember that characteristic x-ray changes in the sacroiliac or apophyseal joints may not develop for months after the onset of symptoms. Do not eliminate the possibility of rheumatoid spondylitis on negative x-rays alone unless persistent symptoms have existed for at least three years.

8. Definite bilateral destructive and/or sclerotic changes in the sacroiliac joints, noted roentgenographically, almost invariably indicate rheumatoid spondylitis.

9. Be cautious in making a diagnosis of rheumatoid spondylitis with unilateral sacroiliac involvement unless other characteristics of the disease are present or unless peripheral rheumatoid arthritis coexists. Persistent unilateral sacroiliitis may be due to tuberculosis.

10. Calcification of the paravertebral ligaments may result from several causes and in itself is not sufficient evidence for the diagnosis of rheumatoid spondylitis; changes in the apophyseal and/or sacroiliac joints must also be present.

11. Remember that the sedimentation rate may be normal in 15 to 20 per cent of cases with active disease and that constitutional symptoms are usually milder than in rheumatoid arthritis involving peripheral joints.

EARLY RISING IN THE PUERPERIUM

GORDON ROSENBLUM, M.D.

LOS ANGELES

HISTORICAL BACKGROUND

The practice of early rising of parturient women dates back to ancient times. Although it was recently stimulated by the wartime shortage of obstetric beds, it did not arise from that emergency. The puerperium, or time of rest given to women in childbed, has varied more widely in the customs of different peoples than any other feature of that great physiologic function of woman.

The biblical Israelites considered the puerpera unclean for seven days after the birth of a male child and for fourteen days after the birth of a female child, during which period she was required to remain at home.¹ The longer period of isolation after a female child has been attributed to their belief that the female sex, being inferior, require a longer period to restore cleanliness. In Athens the puerpera was considered unclean, and whoever touched the mother was forbidden to visit an altar. There can be no doubt that these religious practices in and of themselves enforced a period of at least partial rest during the puerperium. However, the northern tribes of Russia, the Samojedes and others who considered the puerpera unclean often left her

in such a state of isolation and neglect that both mother and child perished.²

In Egypt the wealthier class of women remained in bed three days post partum, but poor women usually resumed their occupations in one day. Syrian women were permitted six days of rest.

The Wakamba of Africa put their parturient women to work after a four day confinement. The North American Indians and other Indian tribes observed no period of puerperium, their women returning to work the day of delivery, following the ceremonial bath, which was often performed in the river.³ In this connection Dr. J. Fields⁴ wrote in 1883 "During two and a half years' life among the Indians I never saw or heard of a case of puerperal fever, puerperal eclampsia or any other diseases peculiar to lying-in women."

Sioux Indian squaws have been known to go into the woods in the cold months of winter and, while there, to give birth to the papoose, which they brought back, together with a load of wood to keep the home fires burning. According to Engelmann, the Apache Indians believed it essential that as soon as the placenta was expelled the parturient be kept upright and walking, for a half hour in order that all clotted blood be expelled from the womb.⁵ The same authority also stated that the Japanese, prior to the nineteenth century, shared in this belief concerning the upright position and kept their parturients propped up in a sitting position for three days before allowing them to recline.

In the Antilles and Guianas food was offered as soon as delivery was completed, and after a few hours the usual labor of the household was resumed by the patient. In old Calabar, in Greenland and among certain Canadian tribes the custom formerly practiced was to allow the delivered woman immediately to resume her household duties while the husband went to bed and received the visits of friends and relatives.⁶

The English obstetrician Charles White⁷ of Manchester wrote in 1793 "The parturient should lie very high with her head and shoulders and should sit up in bed many times a day, especially when she takes food, and as often as she suckles her child, and she should kneel whenever she has occasion to make water, which should be done often. The frequent upright posture is of the utmost consequence and cannot be too much enforced. It prevents the lochia from stagnating, the stools and urine from being too long retained, and promotes the contraction of the uterus, together with that of the abdominal muscles."

In reference to early puerperal rising, Charles White also wrote "The sooner she gets out of bed after her delivery, the better; even on the same day if possible; she should not defer it beyond the second or third at the farthest, and then if it be winter time it will be necessary to have a fire." From his writings it appears that Charles White believed early puerperal rising was a prophylaxis against puerperal fever.

Rotstein⁸ asserted that it had been demonstrated that the early rising of puerperal women necessitated by the London blitz of 1940-1941 did not result in

harm to the patient, and he advocated this method of puerperal management. Several other reports advocating early puerperal rising appear in American and foreign literature. More recently, Black⁷ reported an increased obstetric bed turnover at the Alameda County Hospital, Oakland, Calif., by allowing his patients home early in the puerperium. In his reported series of 3,400 cases about one third were discharged on their fourth day, 30 per cent between the fourth and eighth days and 35 per cent after the eighth day. Although not clearly stated in Black's article, we may presume that most patients were ambulatory at the time of discharge from the hospital. He reported that no complications resulted from this practice. Black concluded after a twelve year program, during which the hospital staff cared for 12,000 deliveries, that a short, active puerperium was safe and desirable. The patients in the entire series were allowed out of bed at varying intervals according to their condition.

Armand⁸ claimed that, in a group of 200 puerperal women in Haiti, early rising prevents thrombosis and embolism, aids uterine involution, helps lochial drainage and fosters quick recovery. He did not observe a single case of inversion, prolapse or retroversion of the uterus. He strongly advocates early rising in the puerperium regardless of the type of delivery. Jorge⁹ allowed only normal puerperal women to get up and reported evident benefit. Vara¹⁰ writes that in the women's clinic at Helsingfors 4,447 women were allowed out of bed very soon after delivery, with resulting improvement in bowel and bladder function and less incidence of thrombosis than in those who were kept in bed for longer periods.

Greenhill¹¹ writes: "Beginning about twenty years ago I gradually cut down the number of days my obstetric and gynecologic patients remained in bed. Now I have progressed so far that, if my obstetric patients cannot urinate spontaneously eight to ten hours after delivery and are uncomfortable as a result of a full bladder, I have them helped out of bed either to sit on a commode or to go to the toilet if there is one in the room. Naturally, women who have bled a great deal or have had complications are not permitted to do this, but at least 90 per cent of parturient women could be permitted out of bed on the first day without harm. . . ." Nelson and Collins¹² reported good results in both obstetric and gynecologic cases in which cotton sutures, together with early ambulation, were employed.

The practice of early ambulation of surgical patients, now a widely accepted procedure, advocated by hundreds of articles in the American and foreign literature, must be considered intimately related to the practice of early puerperal rising. The objectives and underlying principles of the two are identical. Newberger, in a collective review,¹³ presented 189 references advo-

cating early rising of surgical patients. He enumerates the following advantages gained from his study of the literature:

1. Asthenia is minimized.
2. The morale of the patient is lifted.
3. Economy to both patient and hospital is obtained through more rapid convalescence and through reduction of nursing personnel and more efficient use of bed space.
4. Military surgery may be rendered less hazardous.
5. Simplification of postoperative care is obtained.
6. Pulmonary complications are reduced four to five fold.
7. Hollow viscous atony is reduced, with consequent avoidance of use of catheters and laxatives.
8. Wound healing is improved.
9. Thrombosis and embolism are reduced.

Leithauser¹⁴ reported excellent results in several hundred surgical patients who were got up during the first twenty-four hours following surgical operation and claimed that this treatment prevented most pulmonary and circulatory complications. He studied twenty-nine articles from the foreign literature, among which was the particularly impressive report of Zava¹⁵ of 6,000 patients who were got out of bed on the first day without the occurrence of a single case of embolism or eventration. It is interesting to observe that Newberger¹³ showed that the comparative healing of wounds was better in ambulated than in nonambulated rats.

Many observers, including Churchill and McNeile,¹⁶ have noted a definite decrease in the minute volume respiratory exchange of postoperative patients. This decreased respiratory exchange results from such factors as the depression caused by preoperative medication, the use of depressant anesthetic agents and various other factors, such as muscle splinting. Beecher¹⁷ established that this reduction is most pronounced in the first twenty-four hours. Hoerr¹⁸ showed that 50 per cent of all primary postoperative pulmonary complications occur within the first twenty-four hours and that 90 per cent make their appearance before the end of the fourth day. Leithauser¹⁴ reported that spirometer readings showed that vital capacity returned to normal much sooner after early rising.

One of us (G. R.) had advocated and practiced since 1940 the early ambulation of postoperative gynecologic patients. In a report to the obstetric and gynecologic staff of the Cedars of Lebanon Hospital in 1941 he also advised the use of the transverse abdominal incision in obstetrics and gynecology, pointing out that patients operated on in this manner could advantageously be made ambulatory within twenty-four hours. In patients in whom the transverse incisions were made there occurs less postoperative discomfort and there is a lower incidence of postoperative hernias and eviscerations. Consequently patients operated on in this manner can be more safely got up within the first day, as compared to those in whom the more conventional types of incisions are made. Accordingly, in the cesarean sections to be reported later in this paper the transverse abdominal incision was used except when a previous midline incision existed.

With this background of favorable evidence in the literature, the task of studying early ambulation in the

puerperium was begun. At the outset it was realized that there would be objections both from patients and from the medical profession to the practice of early ambulation. The following objections arose during the course of our study:

Objections by Doctors.—1. Fear of medicolegal consequences. 2. Fear that episiotomies would break down. 3. Fear that there might be too much strain on the pelvic floor, resulting in prolapses and retroversions. 4. Fear of excessive postpartum bleeding. 5. Fear that patients would not approve of early rising.

Objections by Patients.—1. That the procedure was unfamiliar to them, therefore they were not sure it was good. 2. That they needed rest and it might tire them too much to get up. 3. That they were too weak to walk. 4. That arising might make them bleed too much. 5. That they might "break their stitches."

We believed that these objections were more theoretical than actual, therefore an attempt to evaluate them accurately was begun.

METHOD OF STUDY

The articles, such as that of Black,⁷ which have advocated mobilization of puerperal women in an intermediate period had led us to the division of our total group of 582 obstetric patients into three groups as follows:

1. Early risers: ambulatory on first or second postpartum day.
2. Intermediate risers: ambulatory on third or fourth postpartum day.
3. Late risers: ambulatory later than the fourth postpartum day.

A consecutive series of 229 unselected patients delivered by us prior to March 1944 was taken from the files in the record room. These patients had all been made ambulatory later than five days post partum. These are called "late risers" and serve as controls. Beginning with March 1944, 106 delivered women, unselected in any manner, were made ambulatory on the third or fourth postpartum days. These women, the "intermediate risers," were given the privilege of going to the bathroom, which was always in the room, instead of using bed pans. In addition, they could eat their meals out of bed if desired, leave the bed to bathe and remain up while the bed linen was being changed. However, the rest of the time they were

unselected series of women who were made ambulatory during their first or second postpartum days. This group, comprising 247 patients, is called the "early risers."¹⁹ Aside from early ambulation, there were no changes made in the management of these patients. Patients delivered by cesarean section were included in this series without selection.

Of a total of 532 patients in our series delivered vaginally 481, or 90.4 per cent, were administered caudal block anesthesia, while 49 of a total of 50, or 98 per cent of patients delivered by cesarean section, were operated on under subarachnoid block.

In our entire series of 582 cases no changes in delivery or operative technic were made. All episiot-

omies were repaired routinely with number 0 and number 00 chromic catgut, without retention sutures. Abdominal incision closures were done routinely with number 0 and number 00 chromic catgut in continuous strands, with a few interrupted sutures placed in the fascia. No retention sutures were used, except when the incision was in the midline.

All patients requiring catheterization were catheterized at least one time for residual urine after voiding had begun, and, if this amount was above 50 cc., catheterization was repeated after each voiding until the amount of residual urine was 50 cc. or less. Patients who voided apparently normal amounts of urine without difficulty and at normal intervals were not catheterized at all. The estimations as to the amount of lochia or of the amount of postpartum bleeding were made from our observations during our rounds at the hospital, in addition to the reports of the obstetric nurses in attendance. Involution of the uterus was ascertained by a vaginal examination made on each patient at the time of discharge from the hospital.

All patients delivered vaginally remained in the hospital six to eight days, depending on the number of available beds, while the patients delivered by cesarean

Catheterization curves for the three groups

section remained eight to ten days. Only 12 patients, or 2 per cent of the entire series, stayed a few days beyond these limits, the majority of these because of minor complications. There were no serious complications in the entire series of 582 patients.

ANALYSIS OF STATISTICS

The study of bladder function, as shown in table 2, reveals that approximately 35 per cent of the early risers required catheterizations averaging three per patient, while approximately 40 per cent of the intermediate and 40 per cent of the late risers required catheterizations averaging four per patient. Table 3 shows that 77 per cent of the total catheterizations in the early group, 69 per cent in the intermediate group and 60 per cent in the late group occurred in the first three postpartum days. There were 5 cases of urinary infection, all of which occurred in the intermediate and late groups.

Analysis of the results in tables 2 and 3 suggests that there is no significant difference as regards bladder function in the three groups of patients.

A study of the chart shows the close similarity of the catheterization curves for the three groups.

19. At the Cedars of Lebanon Hospital the first postpartum day is defined as "the day following delivery."

The contention that early puerperal rising may cause excessive bleeding is disproved by the statistics, which actually show less frequent abnormal bleeding in the early group than in the late group, the intermediate group being approximately the same. Involution of the uterus was uniformly good in all groups.

The fear that early rising would cause a breakdown of episiotomy or abdominal wound incisions is likewise unfounded, only 1 instance of perineal skin separation occurring in the entire series, and this in a patient in the late rising group.

More efficient mobilization of the bowels is evident in table 4, over three times as many spontaneous bowel movements occurring in the early as in the late group.

The total number of complications in the entire series was very small, and there was no significant difference among the three groups. As there were no patients having emboli or thromboses in the entire series, the contention of many previous authors that late rising fosters these complications is not evident in our series. However, we are inclined to believe that study of a much larger series might possibly reveal a lower incidence of these complications in the early risers.

The claim advanced by some obstetricians that early rising may cause later prolapsus and retroversions is also disproved. Of early risers examined at one month and at six weeks, 28.7 per cent had either a midposition or retroversion of the uterus, while 34.6 per cent of the intermediate and 24.4 per cent of the late risers had the same positions—relatively similar totals. This indicates that early rising causes no significant alteration

in which they have noted less abdominal distention and discomfort and a much more rapid convalescence.

No patient in either the early or the intermediate group offered any criticism to us concerning early rising. On the contrary, the majority exhibited enthusiasm, particularly because they did not have to use bed

pans. The multiparas especially were impressed, stating that they felt better and stronger than they had after previous confinements, when they had spent seven to fourteen days entirely in bed.

SUMMARY AND CONCLUSIONS

Our data indicate that delivered women can safely and advantageously get up early in the puerperium with no harmful results occurring.

Bowel function particularly is improved as a result of early rising in the puerperium.

Early puerperal rising reduces the amount of nursing care required.

The majority of patients managed in this way reported favorably on the method.

The statistics show no particular advantage to third or fourth day puerperal rising as compared to the earlier first and second day figures.

It is our opinion that early rising results in more rapid and comfortable convalescence, with less asthenia and less postoperative and postpartum depression.

It is our hope that this study will encourage further interest and continued observation on the question of early puerperal rising which may eventually clarify this still unsettled problem.

in the position of the uterus, at least within a period of four to six weeks following delivery. Prolapsus did not occur in any patient in the entire series.

The nurses working in the obstetric department reported a decided reduction in the amount of nursing care required in patients rising early. They noted better morale and less discomfort in this group. Particularly favorable are their reports concerning cesarean sections,

Determination of Intoxication.—Blood reflects the concentration of alcohol in the brain more directly than does any other obtainable fluid. It has been a standard of reference in all scientific studies dealing with the amounts of alcohol in the body and the physiological effects from the alcohol. No particular difficulty is experienced in obtaining it, and there is no difficulty in the analytical determination of the alcohol. It is easily stored and easily transported. However, for blood, a physician is required to draw the sample and a trained technician to do the analysis. Over and above these requirements there are certain legal obstacles to the procurement of a blood sample. If it were not for these practical difficulties there is little doubt that all authorities would be in thorough accord on the use of blood as the material of choice in the determination of intoxication.—Greenberg, Leon A., in *Alcohol, Science and Society*, New Haven, Quarterly Journal of Studies on Alcohol, 1945.

ST. LOUIS ENCEPHALITIS

OCCURRENCE IN CHILDREN IN THE ST. LOUIS AREA
DURING NONEPIDEMIC YEARS 1939-1944

RUSSELL J. BLATTNER, M.D.

AND

FLORENCE M. HEYS, PH.D.

ST. LOUIS

In the summer of 1933 an epidemic of acute encephalitis occurred in the St. Louis (Missouri) area. From August to November of that year there were 1,097 cases. A filtrable virus isolated from brain tissue of fatal cases was studied¹ extensively and was identified as the etiologic agent. In the summer of 1937 a second outbreak of acute encephalitis occurred in the St. Louis

to differentiate the types and establish the etiology with certainty. From the time of the 1937 epidemic, attempts have been made to ascertain by means of appropriate protection tests whether any of these cases of acute encephalitis was of the St. Louis type. Blood samples were obtained early in the course of the illness, at intervals throughout the hospital stay and at varying times after discharge from the hospital. The development during the clinical course of type specific antibodies to the St. Louis virus was studied by means of protection tests. In certain of the proved cases antibody studies were repeated on blood samples secured from one to three years after the acute attack.

Further efforts were made to differentiate the types of encephalitis by attempted isolation of an infectious agent directly from the spinal fluid. Accordingly, sam-

ples of freshly drawn spinal fluid were inoculated on the retracted chorioallantoic membrane of the developing hen's egg. If changes suggestive of viral growth were noted, usually in three to four days, membranes were triturated and were diluted with tryptose broth, and the supernatant fluid was inoculated intracerebrally into white Swiss mice. At the same time samples of spinal fluid were injected into white Swiss mice intracerebrally and intraperitoneally.

METHODS

Serum was withdrawn from blood samples under aseptic conditions and stored at a temperature of 4 C. St. Louis encephalitis stock virus (Hubbard strain) used for protection tests has been carried by intracerebral inoculation of white Swiss mice since its isolation at autopsy from human brain tissue. Repeated titration of the virus has shown that the minimal lethal dose for white Swiss mice remains between 10^{-8} and 10^{-9} .

MOUSE PROTECTION TESTS

Mouse protection tests, serum-virus neutralization, were used for the detection of antibody in the

serum of a patient and for the demonstration of increasing titer of antibody during the clinical course of the disease.

Serum-virus mixtures were prepared by adding two parts of the patient's serum to one part of appropriate dilution of virus and incubating for two hours in a water bath at 36.5 C. Controls consisted of similar serum-virus mixtures prepared with normal human serum and serum from a rabbit immunized against the St. Louis virus, Hubbard strain. After two hours' incubation these mixtures were inoculated, 0.03 cc. intracerebrally, into adult white Swiss mice. The chart gives the results of a mouse protection test showing rising antibody titer during the course of the illness. Such titer of type specific antibody to the St. Louis virus, increasing during the clinical course, was accepted as evidence that the encephalitis was due to the St. Louis virus.

Results of mouse protection test, showing increase in antibody titer to St. Louis encephalitis virus. Titration of virus used in this test showed the minimum lethal dose to be between 10^{-8} and 10^{-9} .

area. There were 750 cases, and a virus isolated from human brain tissue taken at autopsy was found to be immunologically identical with the infectious agent isolated in 1933. The occurrence of sporadic cases of this disease since 1937 indicates the existence of an endemic focus, a fact of considerable importance from an epidemiologic point of view.

Each year patients are admitted to the St. Louis Children's Hospital with symptoms and signs of acute encephalitis. Clinically it is difficult, if not impossible,

from the Department of Pediatrics, Washington University School of Medicine, and the St. Louis Children's Hospital.

EGG PROTECTION TESTS

In each instance the results of the mouse protection tests were confirmed by means of egg protection tests. The egg protection test² furnishes a relatively simple and inexpensive method for detecting the presence of humoral antibodies and may be carried out by either of two procedures: (1) serum-virus neutralization or (2) protection by passive transfer. In the former, chorioallantoic inoculations consisted of 0.1 cc. of the serum-virus mixtures described. Such inoculated eggs were allowed to continue development for ninety-six hours following inoculation, after which the membranes were stained with trypan blue.³ The degree of neutralization by a given serum sample is indicated by the reduction or absence of virus growth on the chorioallantois. Control membranes were inoculated with comparable mixtures of virus with normal human serum and with immune rabbit serum.

The passive transfer method consists in the passive protection of living cells by immune serum prior to inoculation with virus. Cells of the chorioallantois on contact with specific immune serum are rendered immune⁴ to the corresponding virus, and on subsequent exposure virus growth is prevented. Serum was applied to the chorioallantois by means of an atomizer, 0.3 cc. of serum being distributed over the entire surface of the retracted membrane. Twenty-four hours after being sprayed with serum these membranes were inoculated with 0.1 cc. of virus suspension in serial dilution. Membranes sprayed with normal human serum and membranes sprayed with immune rabbit serum served as controls in each instance.

Serum-virus neutralization and passive transfer methods gave similar results, and both confirmed those obtained by mouse protection tests.

RESULTS

In 1938 Smith, Lennette and Blattner,⁵ reported 10 cases of acute encephalitis studied by mouse protection tests. None of these showed development of type specific antibody to the St. Louis virus.

From 1939 to 1944 inclusive 66 cases of acute encephalitis have been observed in St. Louis Children's Hospital and have been investigated for the development of type specific antibody to the St. Louis virus. Twelve of the 66 cases (18 per cent) showed increasing antibody titer to the St. Louis virus. The clinical findings of these 12 cases are summarized in table 1. Distribution of cases by years and months is presented in table 2. Ten cases reported by Smith, Lennette and Blattner in 1938 are included, bringing the total number of cases to 88.

It will be seen that approximately 74 per cent (65) of all the cases of acute encephalitis occurred in the period from May to October, inclusive; of the cases shown by increasing antibody titer to be St. Louis type, 100 per cent (all 12) occurred in May to October inclusive; 75 per cent of these 12 (9 cases) occurred within the three months period July, August and September.

In 2 of the proved cases of St. Louis type, blood samples obtained two and three years after acute illness showed high titer of antibody.

Table 3 gives the approximate geographic location of cases of acute encephalitis and their distribution by years. It will be noted that no case of the St. Louis type occurred in the city itself, whereas 30 cases which were shown not to be of the St. Louis type did occur in the city proper.

In no instance was the virus of St. Louis encephalitis isolated from spinal fluid either by egg or by mouse inoculation. In 1 case of acute encephalitis occurring in September 1944 the virus of lymphocytic choriomeningitis was recovered from the spinal fluid, and in another, occurring in January 1943, herpes simplex virus was isolated.

COMMENT

The occurrence of sporadic cases of St. Louis encephalitis in nonepidemic years in a district where two epidemics of this disease have occurred previously indicates the persistence of the infectious agent in the area. The fact that all these sporadic cases occurred during the warm months serves to reemphasize the seasonal distribution which was a striking feature of the disease during the epidemics of 1933 and 1937. It is of further interest that a significant number of the sporadic cases has occurred in districts where high per capita incidence was recorded during the epidemics.

While there has been considerable discussion relative to possible case to case transmission by droplet infection, it is significant that, despite numerous attempts, the virus has never been isolated from nasopharyngeal washings and that evidence for direct case to case transmission is lacking. As has been pointed out in a previous publication,⁶ certain epidemiologic features of the disease suggest the possibility that blood sucking vectors may be important factors in its transmission.

6 Blattner, R. J., and Heys, F. M. Blood Sucking Vectors of Encephalitis: Experimental Transmission of St. Louis Encephalitis (Huhbard Strain) to White Swiss Mice by the American Dog Tick *Dermacentor Variabilis* Say, *J. Exper. Med.* 79: 439-454 (April) 1944.

Experimental work,⁷ with an arthropod, the American dog tick *Dermacentor variabilis*, showed for the first time that the St. Louis virus can be transmitted to susceptible animals by the bite of such a vector and that the virus is passed by the infected female tick through her eggs and through all stages of subsequent development. Transovarian passage of the virus was followed into the third generation.

Hammon and his associates⁸ demonstrated the presence of the St. Louis virus in mosquitoes (*Culex tarsalis*) collected in nature during epidemic periods and showed experimentally that the virus can be transmitted by the bite of culicine mosquitoes. However, persistence of the virus indefinitely in the mosquito has not been established.

More recently the presence of the St. Louis virus⁹ has been demonstrated in the bodies of chicken mites (*Dermanyssus gallinae*) collected in nature from three separate localities in St. Louis County during nonepidemic years. These findings might serve to account for the existence of an endemic focus of the infectious agent of St. Louis encephalitis and the occurrence of sporadic cases of this disease in nonepidemic years. Details of epidemiology must await further field and experimental study.

SUMMARY

During the years 1939-1944 inclusive 66 cases of acute encephalitis were studied at the St. Louis Children's Hospital. Twelve were shown to be of the St. Louis type.

All 12 of these cases of St. Louis encephalitis occurred during the months May to October; 9 of the twelve occurred during July, August and September. The occurrence of sporadic cases in the St. Louis area indicates the existence of an endemic focus. Recent advances in the epidemiology of this disease suggest a possible explanation for the persistence of such an endemic focus.

St. Louis encephalitis virus was not recovered from spinal fluid. However, during the course of these investigations the virus of lymphocytic choriomeningitis was recovered from spinal fluid in 1 instance, herpes simplex in another instance.

PRACTICAL ASPECTS OF PEPTIC ULCER MANAGEMENT UNDER SER- VICE CONDITIONS

CAPTAIN JOHN RUSSELL TWISS
(MC), U.S.N.R.

AND

COMMANDER EUGENE V. PARSONNET
(MC), U.S.N.R.

Our purpose in this report is to present the results of an investigation of 82 consecutive cases of peptic ulcer among Naval and Marine Corps personnel, to review factors leading to disability and to formulate principles of diagnosis, management and disposition of military personnel having this condition. To the best of our knowledge no similar report relative to Naval personnel has been published. Because of the increasing prevalence of peptic ulcer among both civilians and military personnel in many of the principal countries at war,¹ a review of recent developments in this field seems justified.

The problems that beset the physician in civilian life in the diagnosis and management of peptic ulcer are well known. In military practice, however, additional factors tend to increase these difficulties. Any consideration of a patient in service must of necessity concern itself primarily with the disposition of the individual in respect to his ability to perform military duties. Particularly the Marine, by the nature of the service expected from him, must be one whose gastrointestinal tract can function well under stress and unusually arduous conditions of subsistence and diet.

GENERAL CONSIDERATIONS

The increasing importance of dyspepsia and particularly peptic ulcer as causes of disability in both civilian and military life has been stressed in many recent reports from England,² Canada,³ Germany⁴ and the United States.⁵ In England the incidence proved high during heavy air raid periods and in forces having military reverses. In Germany, disability was prevalent in war workers and in military personnel before or immediately after going into front lines. In the United States the greatest increase in incidence of these disorders is noted in civilians⁶ and in the Army. Hurst⁷ concluded that "dyspepsia was the largest single disease in the British army, and the most important medical problem of this war."

Paper published under the auspices of the Section on Gastro-Intest. and Proctology.

Peptic ulcer constitutes an important problem in the armed forces because experience in all military services has shown that in general patients with this condition are unfit for service and that a large proportion of these patients had the condition prior to enlistment.⁸ The reported incidence of peptic ulcer among all gastrointestinal diseases is variable. In England it is reported as from 35 to 58 per cent,⁹ in Canadian soldiers invalided home 21 per cent,¹⁰ in United States Army hospitals from 7.2 per cent to 43 per cent,¹¹ in a South Pacific combat zone hospital 19 per cent. In England it has been estimated that 90 per cent of the patients had the condition before enlistment,¹² in the United States the reported incidence is from 50 to 93 per cent.¹³ Duodenal ulcer is far more prevalent than gastric ulcer. The ratio of gastric to duodenal ulcers in the British army is reported as 1:3.6;¹² in the Army hospitals of the United States it varies from 1:8 to 1:49.¹⁴ In Naval personnel the proportion was 1:9.¹⁵

ETIOLOGIC FACTORS

The cause of peptic ulcer is uncertain notwithstanding extensive physiologic, psychiatric and experimental studies.¹⁶ Important contributing factors are conceded to be the excessive secretion of gastric hydrochloric acid and pepsin as well as gastric hypersecretion and hypermotility. All these conditions have resulted from excessive and at times prolonged stimulation of the vagus nerve, either from neurogenic or from psychogenic causes.¹⁷ The same vagus stimulation has been found to produce circulatory changes in the gastric mucosa consisting of anoxia, increased capillary permeability, tissue edema and decreased circulating blood volume.¹⁸ With the physiologic changes described, peptic ulcers have been observed and produced repeatedly.

Psychosomatic medicine has made a great contribution to the practical understanding and management of peptic ulcer by demonstrating the important part that emotional disturbances can play in the formation and

recurrence of peptic ulcer.¹⁹ That the physiologic disturbances described which are associated with peptic ulcer can result from emotional disturbances has been demonstrated by Wolf and Wolff¹⁸ in a laboratory assistant having a permanent gastrostomy opening. Repeated observations in this individual indicated that feelings of hostility, anger or resentment resulted in vigorous contractions of the stomach, a sharp increase in gastric acidity and secretion, and a turgid hyperemic gastric mucosa typical of hypertrophic gastritis. This state was found to be associated with symptoms of pain and heartburn. The turgid mucosa furthermore proved to be abnormally susceptible to injury, ulceration and hemorrhage and to be hypersensitive to direct stimulation.

Palmer²⁰ has contributed a valuable psychosomatic analysis of the factors in the formation of peptic ulcer. He states that heredity and dietary factors, as well as psychosomatic relationships, must be taken into consideration in the study and management of patients with peptic ulcer. The hereditary contribution, frequently overlooked, is that the ulcer patient has a physique which limits his behavior to a certain percentage of his aspirations, which are usually excessively high. The intolerance of these patients to certain types of food is well known. The psychosomatic relationships are primarily concerned with the higher centers and the stomach, which acts in two capacities. One is concerned with its reflex response to foods. The other function is as "an effector unit in the total behavior pattern," in which the stomach responds to psychic stimuli by muscle contraction and gland secretion.

A practical application of the principles described by Palmer is furnished in a psychiatric and physiologic study by Mittelman, Wolff and Scharf²¹ in a series of 30 patients with peptic ulcer. All these patients appeared to be successful and without nervous disorders or life problems. Actually, all proved to have backgrounds of anxiety, insecurity, resentment and hostility. Under usual conditions of living they were relatively comfortable and effective. However, under unusual conditions of stress or disturbing situations produced experimentally, feelings of insecurity and anxiety occurred. These emotional disturbances were almost always associated with an increase in gastric acidity and pepsin secretion. Gastric peristaltic action was greatly increased and frequently pain and sometimes hemorrhage occurred. These investigators conclude that the emotional disturbances and functional changes in the stomach are not cause and effect but "coincident aspects of biologic behavior in reaction to life situations, behavior in some cases being compatible with health, in others resulting in disease."

The importance of these investigations in the diagnosis and treatment of service personnel is evident. Assuming that the so-called "ulcer diathesis" is the unstable type of individual described, the effect under adverse conditions of new situations, new diets (especially K rations) and environmental changes of a military nature may well be reflected in the disability of the

patient. That the civilian can frequently accommodate himself to circumstances of his own making indefinitely but may quickly break down in service is shown by Tidy's comparative studies of civilian and military personnel with peptic ulcer in England.¹²

CLASSIFICATION

Our study is based on a consecutive series of patients with peptic ulcer admitted to the gastroenterologic ward of a large Naval hospital from Nov. 1, 1944 to March 28, 1945. During this time 5,379 patients were admitted to the hospital, of whom 238, or 4 per cent, had disease of the gastrointestinal tract. Of the latter number 82 have been proved cases of duodenal or stomach ulcers, or 35 per cent of all gastrointestinal diseases. Of these, 72 were duodenal and 10 gastric, the ratio of gastric to duodenal ulcers being 1:7. We have further subdivided these groups into those which were service incurred and those in which there was definite evidence that the illness had its onset prior to entry into service.

Duodenal Ulcer.—Service Incurred: Forty of our total of 72 duodenal ulcers, or 55 per cent, were incurred since the patients' enlistment (table 1). An analysis of the statistics reveals the average age in this group to be 28 years and the average duration of symptoms one year and ten months. The average time elapsing between enlistment and the onset of symptoms was two years. Thirty-nine of the 40 patients gave a history of pain and 36 had a typical pain food-relief-syndrome. Twenty-six had nausea or vomiting or both. Hyperacidity was present in only 14, and 15 either gave a history of hematemesis or had at some time had positive laboratory findings of occult blood in the stool. Positive x-ray evidence of activity or residual deformity was found in 39 cases.

Not Service Incurred: Of the 72 cases of duodenal ulcer, there were 32 cases, or 45 per cent, in which there was definite evidence that the condition antedated service (table 1). The average age of this group is 28 and the average duration of symptoms six and one-half years. The average time between enlistment and recurrence of symptoms was six months. Thirty-one of the 32 patients had epigastric pain and 28 gave a history of typical food relationship. Nausea or vomiting has been present in 22 cases. Hyperacidity was found in 14 of the 32 cases and evidence of bleeding in 16. The x-ray diagnosis was positive in all of this group.

Stomach Ulcer.—Service Incurred: Of the 10 stomach ulcers, 6 were incurred in service. The youngest patient was 20 and the oldest 28, and the average duration of symptoms was thirteen months. Five of this group gave a history of pain, 4 of a typical food relationship and 4 of nausea and vomiting. Four had hyperacidity, whereas 3 had evidence of bleeding. Two of these patients had negative x-ray findings; the diagnosis in 1 case was made on the finding of a large prepyloric ulcer during the course of a cholecystectomy for cholelithiasis, and in the second case the diagnosis was based on a classic history and two episodes of severe hemorrhage, for which no other demonstrable cause was found.

Not Service Incurred: In the remaining 4 cases ulcer existed prior to enlistment. The youngest was 19 and the oldest 26, and the average duration of symptoms was five years. All 4 patients had pain, 3 food relationship and 2 nausea or vomiting. Only 1 had hyperacidity, and 2 had evidence of bleeding. All had positive x-ray findings.

The number of stomach ulcers is too small from which to draw any definite conclusions, but of the patients with histories of ulcer antedating service all had shorter intervals of quiescence between enlistment and recurrence than the interval between enlistment and onset of symptoms in the service incurred cases.

DIAGNOSTIC CRITERIA

The important diagnostic criteria are a history of pain, the classic pain-food-relief syndrome and associated nausea or vomiting. Chronicity and periodicity are features that can be elicited frequently. Physical examination is rarely of significance, although many of these patients have a spastic, tender sigmoid. Hyperacidity and hypersecretion are always suggestive, and any evidences of bleeding demands the most careful consideration. Finally, the most conclusive finding is made by x-ray studies.

In the entire series only 3 gave no history of pain, and 2 of these were cases in which the presenting symptom was either hematemesis or tarry stools. Seventy-

TABLE 1.—An Analysis of the Histories and Findings in the Series of 82 Patients Having Peptic Ulcer

	Number of Cases	Average Age	Average Duration of Symptoms	Number of Patients Having					
				Pain	Food Relation	Nausea or Vomiting	Hyperacidity	Evidence of Bleeding	Positive X-ray Findings
Duodenal Ulcer									
Service incurred	40	28 (20-46)	22 mo. (6 wk. to 8 yr.)	39	36	26	14	15	39
Not service incurred	32	28 (18-49)	6½ yr. (2 yr. to 17 yr.)	31	28	22	14	16	32
Totals	72			70	64	48	28	31	71
Stomach Ulcer									
Service incurred	6	25 (20-28)	13 mo. (1 mo. to 2½ yr.)	5	4	4	4	3	4
Not service incurred	4	22 (19-26)	5 yr. (2½ yr. to 7 yr.)	4	3	2	1	2	4
Totals	10			9	7	6	5	5	8

one of the 82 patients were relieved of pain by the ingestion of bland foods. These predominant symptoms, pain and food relief, and particularly bleeding, frequently justify a diagnosis of ulcer, notwithstanding negative x-rays. Corroborative evidence is added by the finding of hyperacidity and (or) hypersecretion, but our observation is that under service conditions such findings are relatively infrequent. We consider gastric contents with over 30 degrees free hydrochloric acid on a fasting stomach or over 40 degrees free hydrochloric acid after a bread test meal to be definitely hyperacid. Hyperacidity was present in 28 of the 72 cases of duodenal ulcer and in 5 of the 10 cases of gastric ulcer. Hypersecretion was present in very few instances.

It will be noted that in only 3 of our patients was there absence of x-ray evidence of ulcer. Such evidence is the finding of a persistent niche with crater, or constant deformity. Frequently in cases presenting vague, atypical histories and with no laboratory findings indicative of ulcer the diagnosis has been based solely on the findings of the roentgenologist. Therefore we feel that despite our best efforts there unquestionably have been some patients whom we have returned to duty with existing but unproved organic lesions.

Peptic ulcer constitutes an important problem in the armed forces because experience in all military services has shown that in general patients with this condition are unfit for service and that a large proportion of these patients had the condition prior to enlistment.⁸ The reported incidence of peptic ulcer among all gastrointestinal diseases is variable. In England it is reported as from 35 to 58 per cent,⁹ in Canadian soldiers inactivated home 21 per cent,¹⁰ in United States Army hospitals from 7.2 per cent to 43 per cent,¹¹ in a South Pacific combat zone hospital 19 per cent. In England it has been estimated that 90 per cent of the patients had the condition before enlistment,¹² in the United States the reported incidence is from 50 to 93 per cent.¹³ Duodenal ulcer is far more prevalent than gastric ulcer. The ratio of gastric to duodenal ulcers in the British army is reported as 1:3.6;¹² in the Army hospitals of the United States it varies from 1:8 to 1:49.¹⁴ In Naval personnel the proportion was 1:9.¹⁵

ETIOLOGIC FACTORS

The cause of peptic ulcer is uncertain notwithstanding extensive physiologic, psychiatric and experimental studies.¹⁶ Important contributing factors are conceded to be the excessive secretion of gastric hydrochloric acid and pepsin as well as gastric hypersecretion and hypermotility. All these conditions have resulted from excessive and at times prolonged stimulation of the vagus nerve, either from neurogenic or from psychogenic causes.¹⁷ The same vagus stimulation has been found to produce circulatory changes in the gastric mucosa consisting of anoxia, increased capillary permeability, tissue edema and decreased circulating blood volume.¹⁸ With the physiologic changes described, peptic ulcers have been observed and produced repeatedly.

Psychosomatic medicine has made a great contribution to the practical understanding and management of peptic ulcer by demonstrating the important part that emotional disturbances can play in the formation and

recurrence of peptic ulcer.¹⁹ That the physiologic disturbances described which are associated with peptic ulcer can result from emotional disturbances has been demonstrated by Wolf and Wolff¹⁸ in a laboratory assistant having a permanent gastrostomy opening. Repeated observations in this individual indicated that feelings of hostility, anger or resentment resulted in vigorous contractions of the stomach, a sharp increase in gastric acidity and secretion, and a turgid hyperemic gastric mucosa typical of hypertrophic gastritis. This state was found to be associated with symptoms of pain and heartburn. The turgid mucosa furthermore proved to be abnormally susceptible to injury, ulceration and hemorrhage and to be hypersensitive to direct stimulation.

Palmer²⁰ has contributed a valuable psychosomatic analysis of the factors in the formation of peptic ulcer. He states that heredity and dietary factors, as well as psychosomatic relationships, must be taken into consideration in the study and management of patients with peptic ulcer. The hereditary contribution, frequently overlooked, is that the ulcer patient has a physique which limits his behavior to a certain percentage of his aspirations, which are usually excessively high. The intolerance of these patients to certain types of food is well known. The psychosomatic relationships are primarily concerned with the higher centers and the stomach, which acts in two capacities. One is concerned with its reflex response to foods. The other function is as "an effector unit in the total behavior pattern," in which the stomach responds to psychic stimuli by muscle contraction and gland secretion.

A practical application of the principles described by Palmer is furnished in a psychiatric and physiologic study by Mittelman, Wolff and Scharf²¹ in a series of 30 patients with peptic ulcer. All these patients appeared to be successful and without nervous disorders or life problems. Actually, all proved to have backgrounds of anxiety, insecurity, resentment and hostility. Under usual conditions of living they were relatively comfortable and effective. However, under unusual conditions of stress or disturbing situations produced experimentally, feelings of insecurity and anxiety occurred. These emotional disturbances were almost always associated with an increase in gastric acidity and pepsin secretion. Gastric peristaltic action was greatly increased and frequently pain and sometimes hemorrhage occurred. These investigators conclude that the emotional disturbances and functional changes in the stomach are not cause and effect but "coincident aspects of biologic behavior in reaction to life situations, behavior in some cases being compatible with health, in others resulting in disease."

The importance of these investigations in the diagnosis and treatment of service personnel is evident. Assuming that the so-called "ulcer diathesis" is the unstable type of individual described, the effect under adverse conditions of new situations, new diets (especially K rations) and environmental changes of a military nature may well be reflected in the disability of the

patient. That the civilian can frequently accommodate himself to circumstances of his own making indefinitely but may quickly break down in service is shown by Tidy's comparative studies of civilian and military personnel with peptic ulcer in England.¹²

CLASSIFICATION

Our study is based on a consecutive series of patients with peptic ulcer admitted to the gastroenterologic ward of a large Naval hospital from Nov. 1, 1944 to March 28, 1945. During this time 5,379 patients were admitted to the hospital, of whom 238, or 4 per cent, had disease of the gastrointestinal tract. Of the latter number 82 have been proved cases of duodenal or stomach ulcers, or 35 per cent of all gastrointestinal diseases. Of these, 72 were duodenal and 10 gastric, the ratio of gastric to duodenal ulcers being 1:7. We have further subdivided these groups into those which were service incurred and those in which there was definite evidence that the illness had its onset prior to entry into service.

Duodenal Ulcer.—Service Incurred: Forty of our total of 72 duodenal ulcers, or 55 per cent, were incurred since the patients' enlistment (table 1). An analysis of the statistics reveals the average age in this group to be 28 years and the average duration of symptoms one year and ten months. The average time elapsing between enlistment and the onset of symptoms was two years. Thirty-nine of the 40 patients gave a history of pain and 36 had a typical pain food-relief-syndrome. Twenty-six had nausea or vomiting or both. Hyperacidity was present in only 14, and 15 either gave a history of hematemesis or had at some time had positive laboratory findings of occult blood in the stool. Positive x-ray evidence of activity or residual deformity was found in 39 cases.

Not Service Incurred: Of the 72 cases of duodenal ulcer, there were 32 cases, or 45 per cent, in which there was definite evidence that the condition antedated service (table 1). The average age of this group is 28 and the average duration of symptoms six and one-half years. The average time between enlistment and recurrence of symptoms was six months. Thirty-one of the 32 patients had epigastric pain and 28 gave a history of typical food relationship. Nausea or vomiting has been present in 22 cases. Hyperacidity was found in 14 of the 32 cases and evidence of bleeding in 16. The x-ray diagnosis was positive in all of this group.

Stomach Ulcer.—Service Incurred: Of the 10 stomach ulcers, 6 were incurred in service. The youngest patient was 20 and the oldest 28, and the average duration of symptoms was thirteen months. Five of this group gave a history of pain, 4 of a typical food relationship and 4 of nausea and vomiting. Four had hyperacidity, whereas 3 had evidence of bleeding. Two of these patients had negative x-ray findings; the diagnosis in 1 case was made on the finding of a large prepyloric ulcer during the course of a cholecystectomy for cholelithiasis, and in the second case the diagnosis was based on a classic history and two episodes of severe hemorrhage, for which no other demonstrable cause was found.

Not Service Incurred: In the remaining 4 cases ulcer existed prior to enlistment. The youngest was 19 and the oldest 26, and the average duration of symptoms was five years. All 4 patients had pain, 3 food relationship and 2 nausea or vomiting. Only 1 had hyperacidity, and 2 had evidence of bleeding. All had positive x-ray findings.

The number of stomach ulcers is too small from which to draw any definite conclusions, but of the patients with histories of ulcer antedating service all had shorter intervals of quiescence between enlistment and recurrence than the interval between enlistment and onset of symptoms in the service incurred cases.

DIAGNOSTIC CRITERIA

The important diagnostic criteria are a history of pain, the classic pain-food-relief syndrome and associated nausea or vomiting. Chronicity and periodicity are features that can be elicited frequently. Physical examination is rarely of significance, although many of these patients have a spastic, tender sigmoid. Hyperacidity and hypersecretion are always suggestive, and any evidences of bleeding demands the most careful consideration. Finally, the most conclusive finding is made by x-ray studies.

In the entire series only 3 gave no history of pain, and 2 of these were cases in which the presenting symptom was either hematemesis or tarry stools. Seventy-

one of the 82 patients were relieved of pain by the ingestion of bland foods. These predominant symptoms, pain and food relief, and particularly bleeding, frequently justify a diagnosis of ulcer, notwithstanding negative x-rays. Corroborative evidence is added by the finding of hyperacidity and (or) hypersecretion, but our observation is that under service conditions such findings are relatively infrequent. We consider gastric contents with over 30 degrees free hydrochloric acid on a fasting stomach or over 40 degrees free hydrochloric acid after a bread test meal to be definitely hyperacid. Hyperacidity was present in 28 of the 72 cases of duodenal ulcer and in 5 of the 10 cases of gastric ulcer. Hypersecretion was present in very few instances.

It will be noted that in only 3 of our patients was there absence of x-ray evidence of ulcer. Such evidence is the finding of a persistent niche with crater, or constant deformity. Frequently in cases presenting vague, atypical histories and with no laboratory findings indicative of ulcer the diagnosis has been based solely on the findings of the roentgenologist. Therefore we feel that despite our best efforts there unquestionably have been some patients whom we have returned to duty with existing but unproved organic lesions.

TREATMENT

The treatment shall be described in slight detail, since we believe that the general pattern is followed with little variation in the majority of institutions. The general principles have been described by Winkelstein²² and Aaron.²³

All patients admitted with an established diagnosis, or in whom the existence of ulcer is strongly suspected, are put on complete bed rest with only bathroom privileges, a diet of milk and cream every two hours, medication consisting of Amphojel or other antacid medication, belladonna, mild sedation and supplementary vitamins. Bed rest is continued for a two week period. The diet is increased each week until at the end of three or four weeks patients are taking a full modified type of Sippy diet. Medication and smoking restriction are continued throughout the course of treatment.

The length of time for treatment and modifications of the routine vary according to the individual response. The degree of improvement is estimated on the basis of the amelioration of subjective symptoms and the findings of an x-ray study performed six weeks following the original x-ray. Whereas in some cases it may be

necessary to prolong the period of definite dietary restriction or bed rest, nevertheless the majority of patients show evidence of rapid improvement and at the end of two or three weeks complain only of vague and occasional epigastric distress. Outside "liberty" with its temptations to dietary and other indiscretions is not granted until the patient is free from symptoms. Medical treatment is continued until the patient is able to tolerate a full Sippy diet without medication, a regular diet with certain restrictions as related to foods which the individual finds he does not tolerate well, or until it is established that there exist certain indications for operative intervention.

As concerns operative treatment, we are in accord with the writings of Lahey.²⁴ At the writing of this report one of us has performed subtotal gastrectomies on 4 patients in this series. Three were duodenal ulcers, in 2 of which there was almost a complete lack of response to medical treatment after a month of rigid routine, the third case having been one in which two severe episodes of intestinal bleeding had occurred and

in which an interval operation was performed. In the fourth case, a large prepyloric crater was found during the course of a cholecystectomy, and a resection was performed. The type of operation is modeled after that described by Hofmeister, and we prefer the antecolic, long loop anastomosis. All 4 patients made uneventful operative recoveries, but it is too early at this date to estimate the ultimate results. We should like to substantiate the findings of other surgeons who have found that early mobility greatly aids in the immediate postoperative period. Our patients are permitted and encouraged to move about after the effects of the anesthesia have subsided. They are given bathroom privileges at once and by the third postoperative day are able to walk about freely with but little discomfort.

It is important at this time to mention a factor in the treatment of ulcer patients that is of the greatest value, namely the control of exciting emotional factors. We have found the most striking evidence of this in patients in whom for one reason or another there has been a failure to make a diagnosis. Such patients are sometimes told that they have "nervous stomachs," are "unstable" or just have "nothing the matter with them." The improvement invariably is most noticeable and pronounced, once the patient discovers that he has some tangible disease which is expected to respond to treatment.

The individuals coming under our observation have varied in age between 18 and 46. They have been white and black, tall and short, fat and thin, nervous and phlegmatic. There is no common physical habitus, but the one common denominator is an unstable or maladjusted psychogenic and physiologic background. Marital difficulties, money matters, uncertainty as to ultimate disposition are only a few of the great number of problems that make so difficult the treatment of such patients. We have made as great an attempt as our ability and time permit to try to understand the individual and to be of assistance to him in allaying the exciting psychic factors.

RESULTS OF TREATMENT AND DISPOSITION

The results of treatment are interpreted primarily by clinical response and x-ray findings. We have had occasion to make follow-up x-ray studies in 46 instances. These studies, made at the end of six weeks of treatment, revealed no evidence of any organic lesion in 20 cases, a lessening in the size of the crater in 10, residual deformity but no crater in 8 and demonstrated no change in 8. It has been observed in a number of our cases that the clinical improvement is not proportionate to the findings of repeated x-ray examination; some patients who are symptom free still having positive x-ray findings, and others with a negative x-ray interpretation still complain of clearcut subjective symptoms. We classify our clinical results in accordance with the patient's ability to tolerate various levels of diet.

Of 40 patients with service incurred duodenal ulcer under treatment for six weeks, 26 were able to tolerate a full Sippy diet without medication and without discomfort, 3 were partaking of a regular hospital diet without complaints, 9 have shown slight improvement and 2 showed no improvement. Thirty-two of these 40 patients were Marine personnel. Of those, 26 have been discharged from service and 3 were returned to "limited duty." (This term means duty limited to the continent of the United States.) There were in this

24. Lahey, F. H.: Inflammatory Lesions of the Stomach and Duodenum, *J. A. M. A.* 127: 1030 (April 21) 1945.

group 3 with subtotal resections, 2 of whom were returned to limited duty, the other having been discharged from service. Naval personnel in this classification numbered 8. Three have been discharged from service, 5 were returned to "limited duty," 1 having had a gastroenterostomy performed. In the latter instance a partial gastrectomy was deemed inadvisable because of the extensive inflammatory reaction surrounding the lesion (table 2).

Of 32 patients with duodenal ulcer incurred prior to enlistment, 11 showed slight improvement and the remainder were able to tolerate a full Sippy diet. Practically none, however, were able to tolerate a regular hospital diet, which is the one primary prerequisite for return to duty. Of these 32 patients 23 were Marines, all of whom were discharged from service. Of the 9 Naval personnel, 7 were discharged from service and 2 were returned to limited duty.

In 6 of the 10 patients with stomach ulcer the ulcer was service incurred. Of these, 2 had been operated on for perforation prior to their admission to this hospital and were discharged from service able to tolerate a full Sippy diet. One patient was operated on at this hospital for cholelithiasis, and during the operation a large prepyloric crater was found and a subtotal resection was performed. This patient has returned to limited duty. The remaining 2 patients were discharged from service, 1 as slightly and the second as much improved.

In the remaining 4 patients with stomach ulcer the ulcer was not service incurred. All 4 have been discharged from service having shown considerable improvement under medical treatment, although in 2 of these cases, in spite of normal gastric analyses and gastrointestinal x-ray studies, there were still present mild subjective complaints on a moderately restricted diet.

A further breakdown of our statistics shows that there have been 63 Marines and 19 Naval personnel in this series. Of the 63 Marines, 57 have been released from service and 6 retained. Of the 19 Naval personnel, 12 have been discharged and 7 retained. These figures reflect quite accurately our estimates as to the different character of duty required by these two branches of service.

It also will be noted that in the 82 patients with peptic ulcer the ulcers of 46 were service incurred. Thirty-five of these have been released from service and 11 have returned to limited duty. Among the 36 patients with ulcer not service incurred, only 2 have returned to duty whereas the remainder have been discharged. Thus we see the somewhat less favorable response to treatment in those cases in which the symptoms are of longer duration.

There remains to discuss the contributory effects of service conditions to the incidence of ulcer. Among the patients with duodenal ulcer the average length of time between enlistment and onset of symptoms in patients having had duodenal ulcer prior to enlistment was approximately six months, whereas in those having ulcers incurred in line of duty the average period between enlistment and disability was two years. Few of our patients had reached combat areas and rarely was the onset of symptoms related to such conditions. However, field conditions and particularly field "chow" frequently precipitated digestive symptoms. The con-

clusions which seem justified by these facts are that the psychogenic constitutional states of these individuals, together with problems of military service and the attendant physiologic disturbances, are the essential factors in the production of their ulcers. We further feel justified in stating that the attendant emotional and physical stress placed on many of these already unstable and (or) maladjusted individuals has caused an earlier incidence of symptoms than might have been the case during the uninterrupted course of an adjusted civil life.

Finally, as a result of our experience we are convinced that any individual with a history of ulcer should not be admitted to service. The short period of time elapsing in the average case between enlistment and disability precludes any great degree of usefulness on the part of the patient and is certain to cause a great many sick days and to render return to active civilian work complicated and uncertain. Furthermore, the disposition of patients with service incurred lesions can be decided on in a shorter time than has been customary heretofore. We recommend early separation from service in these cases also, especially if the individual shows any signs of psychosomatic disturbance such as emotional instability, unless his military duties are of a very specialized, noncombative character.

SUMMARY AND CONCLUSIONS

1. The ulcers in this series of 82 Marine and Naval personnel patients were incurred before enlistment in 55 per cent of the cases, in line of duty in 45 per cent. Disability occurred in an average time of two years in patients with duodenal ulcer not having the condition previous to enlistment. Those having a history of previous ulcer were disabled within six months. Few reached any combat areas.

2. The most reliable diagnostic criteria are considered a history of pain, particularly related to meals, evidence of hemorrhage and positive x-ray findings of ulcer.

3. Treatment has consisted in the use of a progressive modified Sippy type of diet with initial feedings every two hours, antacids, belladonna and vitamin supplements.

4. All patients are treated for a minimum period of six weeks with an initial period of two weeks' bed rest. Smoking is prohibited. No liberty is granted until the patient is symptom free and able to tolerate a regular diet.

5. No patient is considered a candidate for limited duty unless he can tolerate a regular diet without medication and has no evidence of an unstable emotional background.

6. Patients with proved peptic ulcer are usually discharged from the service. Limited duty within the continental limits of the United States has been recommended in a limited number of cases if the individual is particularly desirous of returning to duty, is unusually qualified from the point of view of training or experience, and there is a reasonable likelihood that the type of duty to which he returns is not too arduous and will permit of a certain amount of dietary discretion.

7. No patient with a history or findings of peptic ulcer, in our opinion, should be admitted to the armed forces. Early separation from service is recommended in all cases of peptic ulcer.

ABSTRACT OF DISCUSSION

DR. SARA M. JORDAN, Boston: Of considerable significance for postwar civilian life is the difference noted in average time between enlistment and onset of symptoms in the service incurred group (two years) and between enlistment and recurrence of symptoms in the group of ulcers not service incurred (six months). These data suggest that in persons who have an ulcer diathesis, an actual occurrence of ulcer increases the susceptibility. In my clinical experience I have been impressed with this fact and for this reason have stressed the importance of prophylaxis of this disease in ulcer prospectives. A serious effort should be made to detect those individuals who have symptoms of pylorospasm or hyperchlorhydria and x-ray evidence of pylorospasm and duodenal spasm, and, having detected them, we should make every effort to protect them against actual occurrence of ulcer with good hygiene, a reasonably careful diet and the omission of smoking. It is also important to treat ulcer intensively at its first occurrence and in this treatment to include adequate instruction concerning subsequent prophylaxis. Those of us who see ulcer complications in their most disastrous forms are constantly impressed with the fact that early intensive care could have prevented them. There is undoubtedly much less overtreatment than undertreatment of early ulcer. As Drs. Twiss and Parsonnet have indicated, the diagnosis of ulcer must often be made without the actual demonstration of a crater. Irritability of the duodenum with no actual ulcer defect may be the only radiologic finding, but, if this is associated with the subjective findings of ulcer, treatment should be instituted. Very often later x-ray examination shows a constriction in the second portion of the duodenum or an actual retraction deformity of the cap. The disappearance of irritability is, in my experience, the best x-ray guide to improvement and healing.

COLONEL JOHN L. KANTOR, M. C., A. U. S.: This report shows that Navy experience with peptic ulcer coincides closely with that of the Army. It is unfortunate that so many ulcer subjects have been inducted into the military services. Forty-five per cent of the authors' cases fall into this category, and this seems pretty much the general experience. Can something more than the present screening at induction stations be done to improve the situation? About ten years ago I recommended (*Mil. Surgeon* 74:113 [March] 1934) that inductees presenting a history of ulcer be handled as follows: A certain number might be disposed of at draft or examining boards, where it is merely a question of checking up on readily accessible data such as previous operations or diagnoses by reliable physicians or hospitals. All other ulcer suspects or ulcer claimants should be immediately hospitalized in army or navy general hospitals, where sections of gastroenterology would already be set up and in operation. It would then be the duty of the gastroenterologists to make appropriate studies and to decide between immediate rejection or acceptance for full or for limited service. By not allowing such inductees to perform any military or naval duty before hospitalization and by promptly discharging all proved ulcer cases, the service aggravation of pre-existing ulcers would be greatly reduced if not completely eliminated, thus saving the government large sums that would otherwise be paid out to meet disability claims. As to the disposition of ulcer patients, I am in general agreement with the authors. Non-service incurred cases should be discharged unless the subject is so valuable to the service that he can be given special opportunities to follow a proper diet and work in a favorable environment. Service incurred cases should be strictly individualized. Some will have to be discharged, to be sure; yet it should be noted that the arbitrary dismissal of a professional soldier or sailor, especially in the case of an officer, is as much of a psychic shock to him as is the retention in service of an unhappy civilian. In short, every effort should be made to retain trained veterans whose services are needed and who desire to continue on active duty.

CAPTAIN A. M. SNELL (MC), U.S.N.R.: The statistics on this subject, as presented by the authors, appear to be in close agreement with the general impressions which I have gathered from eighteen months' observation of patients in the gastrointestinal service of a West Coast naval hospital. Roughly, two thirds of our patients had ulcer symptoms prior to enlist-

ment, a fact which is not always given in the health record and which not infrequently requires investigation and verification by the Red Cross authorities near the patient's home. A large percentage of our patients have had foreign duty, and many of them have been in actual combat. There is no doubt that many of them would have carried on successfully in civilian life had not the psychogenic factors mentioned by the authors intervened. Living conditions on ships and shore stations in combat areas, the arduous duties required of many of our patients and their anxiety about their own situation and that of their families are obviously responsible for the reactivation of many quiescent ulcers. Return to the United States, a brief period of leave and a more normal mode of life are productive of complete symptomatic relief in many patients, and neither prolonged medical treatment nor surgery is often required. The authors mention "anxiety, insecurity, resentment and hostility" in their discussion of psychosomatic factors; the importance of these factors in men in combat areas can hardly be overestimated. In a not inconsiderable number the existence of an ulcer becomes, either consciously or subconsciously, a means of escape from a hazardous and unpleasant existence. I have been impressed at this hospital with three other matters of clinical importance: (1) the high percentage of patients who relate bizarre or atypical histories, although roentgen evidence of ulcer is indisputable; (2) the relatively small number of patients who have neither pronounced hyperchlorhydria nor hypersecretion, and (3) the relative rarity of complications. Free perforations or inflammatory penetrating lesions are rarely seen; hemorrhage of a major degree is not often a problem; and obstruction, except that of a transient nature incidental to pylorospasm, is almost unknown. I agree with the authors that the man with a peptic ulcer rarely has a useful place in military service. A few devoted individuals carry on in spite of an ulcer, and one occasionally encounters officers or petty officers who have performed long and useful duty both before and after necessary gastroduodenal surgery. To do so obviously requires a temperament not ordinarily encountered in an ulcer-bearing individual.

DR. A. H. AARON, Buffalo: One is impressed by the evidence indicating the etiologic importance of psychiatric trauma in peptic ulcer. There is definite agreement today that this results in alterations in secretion, motility and tone of the gastrointestinal tract conducive to peptic ulcer formation. It is interesting to note that 32 of the authors' patients evidently had peptic ulcer previous to their entrance into the armed forces. It seems difficult to explain how they were accepted, but having worked for a period on an induction team I can readily testify to the difficulty of obtaining an adequate history that would suggest the presence of peptic ulcer. Even after having secured such a history, one frequently finds the x-ray findings negative, and in view of this it was impossible on the suggestive history alone to exclude the individuals from military service. The symptoms of nausea and vomiting have not impressed me as of diagnostic significance in uncomplicated peptic ulcer such as we see in young adults with an average history of slightly more than a year's duration. These symptoms are more often an indication of the complicating factor of pyloric obstruction due to edema, spasm or scar tissue. I wonder if the incidence of these symptoms in their group of cases bears any relation to what has appeared in the literature as manifestations of acute psychiatric upsets occurring during the course of the war effort. I agree that medical treatment must aim toward as near as possible control of the acid peptic secretion and protection against psychiatric shock. From the surgical point of view I think the group of irreplaceable individuals on whom Walters and Butt did a resection relatively early in order to shorten the period of treatment is a very significant event and one which we may have to apply occasionally in civilian practice. The etiologic factor of emotional strain is the most difficult to control, in view of the fact that a large percentage with cardiospasm, diarrhea of undetermined origin, chronic ulcerative colitis and peptic ulcer have the same basic background of emotional instability. Why this group develops these wide divergences of conditions is not clear. In private practice I have been impressed by a careful searching history, confirmed

by x-ray, by the high indications of peptic ulcer in the teen age period. I do not know of any one better equipped than Commanders Twiss and Parsonnet to state that these patients with peptic ulcer should not be admitted to the armed forces and that, if they should enter the service and develop ulcers, early separation from service be recommended. On the other hand, in private practice these patients will have to be adjusted to continue to earn a living and carry on as near as possible the normal functions in the highly competitive field of living. We may be able to suggest change of occupation, but here again one is disturbed by the finding of peptic ulcer in the most diverse types of work, and it narrows it down to the fundamental discussion of the individual with the ulcer and the efforts of the private practitioner who sees these patients early to emphasize the advisability of early, properly controlled treatment. At the present moment those who are interested in the care of peptic ulcer are advocating a form of therapy that can be carried out by every practitioner utilizing a small group of medicinal agents, a generous simplified diet and definite personal interest in each patient. Under these circumstances it may be possible to avoid the serious complications of the disease.

CAPT. J. R. TWISS (MC), U.S.N.R.: We are entirely in agreement with the conclusion of Dr. Jordan relative to the importance of the recognition of patients having an ulcer diathesis and instituting, as soon as possible, active treatment as well as prophylactic treatment for the purpose of preventing recurrences as far as this is possible. The prompt breakdown of patients who have previously had ulcer, after coming into service, is due in no small measure to the complete inability of the medical officer to control conditions for the purpose of preventing recurrent ulcer symptoms. We are, furthermore, in full agreement with the proposal of Colonel Kantor that all patients giving a history suggestive of ulcer should be fully investigated before being admitted to the armed forces. This procedure would relieve the government of a tremendous and unnecessary financial liability in the treatment of these patients, who are of no actual value to the service after having been accepted. Our objective in regard to the retention of experienced men who desire to remain in the service, as far as circumstances permit, is in accordance with the policy expressed by Colonel Kantor. Captain Snell has shown a very practical grasp of the problems with which we have had to contend, especially in his recognition of the fact that the patient with peptic ulcer tends to utilize his knowledge of having this condition as an admitted means to obtain a discharge from the service. We feel that all patients admitted with suggestive symptoms or with a diagnosis of gastrointestinal disease should have the benefit of a gastrointestinal series. In those having no positive x-ray evidence, the diagnosis of peptic ulcer is never made, unless the history and other diagnostic findings provide what we consider incontestable evidence of this condition. Dr. Aaron's contention that in most young people the symptoms of nausea and vomiting are of functional origin is well borne out by our series of patients, in that practically none showed x-ray evidence or operative findings of obstruction sufficient to account for these symptoms.

Polioomyelitis.—Despite thirty years of concentrated clinical, epidemiological and experimental study, polioomyelitis remains as an outstanding challenge to preventive medicine. No means of preventing or curing the acute stage of the disease is yet in sight. There is equally no adequate knowledge on which to base any straightforward account of the natural history of the disease. . . . Polioomyelitis, in its clinically visible form of fever and signs of central nervous system infection followed by more or less extensive paralysis, is known to be due to invasion by one of the smallest viruses. The virus can produce essentially similar infections in several species of monkey but, except for a small proportion of strains, in no lower type of animal. The more important characteristics of the virus and the pathology of experimental infections have been fully elucidated, but a great deal remains to be learnt in regard to the epidemiology of the disease.—Burnet, Frank MacFarlane: *Virus as Organism*, Cambridge, Mass., Harvard University Press, 1945.

TREATMENT OF DIABETIC ACIDOSIS AND DIABETIC COMA

THOMAS P. ALMY, M.D.
KATHARINE SWIFT, M.D.
AND
EDWARD TOLSTOI, M.D.
NEW YORK

Although the agents available for the treatment of diabetic acidosis have remained the same for many years, there is today no universally accepted procedure in the management of this common medical emergency. No one will deny that the two most urgently needed substances are insulin and isotonic solution of sodium chloride, but worthy of critical review are (a) the desirability of administering glucose in the early phases of therapy, (b) the need for frequent determinations of blood sugar and carbon dioxide combining power in regulating the treatment, (c) the optimum size of the doses of insulin, and their frequency of administration, and (d) the need for the constant attendance of a team of specialists in the field of diabetes mellitus to guide the therapy.

At the New York Hospital, during the past five years, nearly all patients with diabetic acidosis and diabetic coma have received liberal amounts of glucose by mouth, by vein or by both routes from the time of admission. The course of therapy has been followed almost entirely by clinical signs and by qualitative tests for sugar, acetone and diacetic acid in the urine. The blood sugar and carbon dioxide combining power have rarely been used as indexes of the severity of the disorder or of the progress of treatment, and indeed these estimations have been made, in most instances, only after recovery from ketosis. The individual insulin doses have been small and repeated frequently. All but a few of our cases have been treated by the intern, with advice from the medical resident physician. As these practices differ considerably from those advocated by such authorities as Joslin¹ and Root,² we have been led to review the results of our therapy. The facts obtained are the basis of this report.

METHOD OF TREATMENT

Interns are instructed to treat diabetic acidosis and diabetic coma as follows:

1. As soon as the diagnosis is made, give 25 units of regular insulin subcutaneously and repeat this every half hour until the patient is free from all signs of ketosis, as judged by clinical and laboratory evidence.
2. When possible, replacements of fluid, salt and carbohydrate should be given by mouth. Give in each hour (a) 50 to 75 Gm. of glucose as orange juice (500-750 cc.), grape juice (300-450 cc.) or fortified fruit juices; (b) salty broth, 200 cc.; (c) enough water to make the total fluid intake 1,000-1,500 cc.
3. If the patient is drowsy or comatose, or if the patient has vomited or has been nauseated during the preceding twenty-four hours, therapy must be begun by the intravenous route: (a) Infusion of 5 per cent glucose in isotonic solution of sodium chloride, which should run in at first at the rate of 750-1,000 cc. per hour. (b) The rate of this infusion should be reduced

as soon as dehydration is relieved. Patients over 40 years of age, any with notable arteriosclerosis and any with cardiovascular disease may have to be infused at slower rates and should be observed frequently and with extreme care for signs of increased venous pressure and passive congestion of the lungs.

Return to the oral route as soon as the patient is fully conscious and free from nausea.

4. Test a urine specimen every half hour or every hour for sugar, acetone and diacetic acid. (Catheterize if necessary.) Continue the foregoing therapy until the urine is free from acetone and diacetic acid. Do not leave the ward until this is accomplished.

5. When ketonuria and all clinical signs of acidosis have disappeared, give fruit juice and 25 units of insulin at two hour intervals for at least eight more hours.

6. If the patient is anuric, guide the therapy by frequent estimations of the carbon dioxide combining power of the blood. This rule will also apply if acidosis should occur without the presence of acetone bodies

in the urine. (Such cases are exceedingly rare and have not yet occurred in our experience.)

Every patient whose urine contains sugar and acetone bodies is treated thus, regardless of the severity of the diabetic acidosis. Many of the milder cases so treated have been excluded from the series reported here, but no fatal case has been excluded, nor any in which the acidosis did not promptly respond to treatment.

This report concerns all cases of diabetic acidosis and diabetic coma admitted to the New York Hospital from Jan. 1, 1940 to Dec. 31, 1944 which satisfied the following criteria: 1. Ketonuria, determined by the ferric chloride reaction for diacetic acid and/or the nitroprusside test for acetone. The test for acetone was read as 3 plus or 4 plus in all but 5 cases, in which a 2 plus reaction was associated with severe clinical signs of acidosis. 2. One or more clinical signs of acidosis, as listed in table 5. 3. The requirement of at least 75 units of insulin over a period of three hours to eliminate ketonuria.

There were 99 such occurrences in 71 patients; 28 of the patients were men and 43 were women. The age distribution is shown in table 1. Twenty-two, or 31 per cent of the patients, were over 40 years of age.

The duration of diabetes prior to admission for diabetic acidosis is shown in table 2. In 13 instances the existence of diabetes was not previously suspected, and in 27 instances the patient had been treated for diabetes for five years or more. This distribution is similar to that reported by Joslin.³

In table 3 are summarized the daily insulin requirements of these patients before or after hospitalization. These amounts of insulin were sufficient to produce

good clinical control by our criteria, namely maintenance of weight, freedom from symptoms of diabetes, freedom from ketosis and absence of insulin reactions. We are impressed that the "mildness" of diabetes, as indicated by the need for little or no insulin, is not a guaranty against acidosis.

In table 4 are listed the precipitating causes of diabetic acidosis in these patients. It is confirmed here that infection and omission of insulin are the most important causes of acidosis. On evaluating the dietary intake over the last few days before admission, it was found that 25 patients had eaten less than their usual diet and that only 2 had eaten more. One of these 2 patients had run out of insulin the day before admission. The other patient had stopped taking insulin two days before admission and during this period had eaten her usual diet plus a large quantity of peanuts. In most publications, one of the important causes of ketosis in a diabetic patient is given as "dietary indiscretion," and this is often interpreted as eating concentrated sweets or other foods in addition to the permitted diet. After our experience we find it difficult to accept the dictum that overeating per se is a cause of diabetic acidosis.

The clinical signs and symptoms exhibited by these patients are presented in table 5. Coma is defined by us as a state of unconsciousness in which the patient fails to respond to any stimulus, and thus the 3 patients

3. Joslin, E. P.; Root, H. F.; White, Pricilla; Marble, Alexander, and Hunt, H. M.: Diabetic Coma, *M. Clin. North America* 16: 791 (Jan.) 1933.

in that category belong in "stage 4" of coma as defined by Rabinowitch.⁴ All cases in which the condition was described as drowsy, semicomatose or in other ways indicating impairment of the sensorium with some responsiveness are here listed as semiconscious. Thus slightly over half of the patients had disturbances of the sensorium and fall into the various categories of coma outlined by Rabinowitch.⁴ Only 1 patient was in circulatory shock, and this patient only developed anuria. In 46 of the cases there was an infection in association with diabetic acidosis, and in 22 it was so severe as to constitute by itself an indication for hospitalization.

The total amounts of insulin, glucose, sodium chloride and fluid administered in the first twenty-four hours are given in table 6. Only 2 patients received single insulin doses greater than 50 units, and 1 of these was a case of proved insulin resistance (fatal case 7). A few of the patients received protamine zinc insulin during the first day in the hospital, but in general it has been our custom to postpone the use of slower acting insulin until at least two days after entry. In 27 of the cases, sixth molar sodium lactate was given intravenously.

The interval required to relieve ketosis was estimated from the time of disappearance of ketonuria. This

TABLE 6.—Quantities of Therapeutic Agents Given in First Twenty-Four Hours

could be determined accurately in 95 cases. From table 7 it can be seen that 20 of these (21 per cent) remained in ketosis longer than twelve hours.

Table 7 reveals that the time of recovery was about the same irrespective of the route of administration of glucose. The patients in whom recovery was delayed did not receive more glucose than those who recovered more rapidly: The median intake of glucose in the first twenty-four hours by these patients is exactly the same (312 Gm.) as that reported for the entire series in table 6. The patients in whom recovery was delayed beyond twelve hours did, however, receive less insulin in each hour than is desirable. Although we recommend a constant dosage of 50 units of insulin per hour until recovery, only 1 of these patients received that amount. The rest received from 4 to 27 units per hour, with a mean dosage of 12 units per hour. We are led to conclude that delay in recovery was associated not with the excessive intake of glucose but with inadequate dosage of insulin.

There were 7 deaths in this series. The salient features are presented in table 8, and the protocols are given herewith:

CASE 1.—A man aged 55 was admitted with coronary occlusion and mild diabetic ketosis. He was completely conscious throughout. The ketosis was cleared in eight hours with 150 units of insulin, oral glucose, oral and parenteral fluids and salt in limited quantities. There was no ketosis in the ensuing twenty-eight hours, until death. Autopsy showed two fresh myocardial infarcts, with aneurysm formation and beginning rupture of the ventricle.

4. Rabinowitch, I. M.; Forster, A. F., and Berslev, F. H.: *Diabetic Coma*, Ann. Int. Med. 12:14 (April) 1939.

CASE 2.—A woman aged 49 had acute purulent frontal sinusitis due to hemolytic *Staphylococcus aureus*, with cellulitis of the face, left exophthalmos and ophthalmoplegia. Her urine on admission contained 2 plus acetone and 2 plus diacetic acid, and the patient was drowsy. She was cleared of ketosis in eight hours, using 125 units of insulin plus intravenous sodium lactate and oral and intravenous glucose. Despite this therapy

TABLE 7.—Duration of Ketonuria

Total.....	28	100	67	100	95	100

her mental state did not improve, and she later became completely comatose. Lumbar puncture showed turbid spinal fluid with 150 white blood cells per cubic millimeter. Ketosis did not reappear in the remaining forty-eight hours of her life, although the temperature remained between 39 and 40 C. (102.2-104 F.). She had massive edema of the orbits and face, unrelieved by surgical drainage of the frontal and ethmoid sinuses, together with the removal of necrotic frontal bone. The patient was further explored through burrholes by the neurosurgeon, who found no localized intracranial abscess and felt that she had a cavernous sinus thrombosis. Despite adequate penicillin therapy she died on the third day in the hospital.

CASE 3.—A woman aged 40 was admitted with cellulitis of the neck and severe diabetic acidosis. She was semicomatose. In another service of our hospital, to which she was admitted, ketosis was cleared only after twenty to twenty-four hours, intravenous glucose and sodium lactate being used and only 160 units of insulin. She then relapsed into acidosis, which was finally cleared forty-five hours after admission and twenty-

TABLE 8.—Fatal Cases

Case, Sex, Age	Mental Status	Duration of Ketosis	Interval Free of Ketosis Before Death	Associated Conditions	Autopsy
1 ♂ 55	Conscious	8 hrs.	23 hrs.	Myocardial infarcts	Yes
2 ♀ 49	Semiconscious	8 hrs.	15 hrs.	Sinusitis, cellulitis, probable cavernous sinus thrombosis	No
3 ♀ 40	Semiconscious	45 hrs.	22 hrs.	Staphylococci septicemia and pneumonia	Yes
4 ♀ 43	Conscious	6 hrs.	4 days	Cirrhosis; type 1 pneumococcal pneumonia with bacteremia	Yes
5 ♀ 77	Semiconscious	14 hrs.	8 days	Fractured neck of femur, generalized atheromatosis; thyrotoxicosis	Yes
6 ♀ 53	Conscious	2 hrs.	0	Lobar pneumonia	No
7 ♀ 50	Comatose	45 hrs.	0	Insulin resistance	Yes

two hours prior to death. During this time the temperature fluctuated from 39 to 41 C. (102.2-105.8 F.). The patient developed pneumonia and septicemia; both blood and sputum cultures were positive for hemolytic *Staphylococcus aureus*, the blood culture showing 12 colonies per cubic centimeter. At this time she was transferred to our service, but she died seven hours later in pulmonary edema. Autopsy showed carbuncle of the neck, septic infarcts of the lungs, bronchopneumonia of all lobes and bilateral empyema, all due to the hemolytic *Staphylococcus aureus*.

CASE 4.—A man aged 43 was admitted in diabetic ketosis, lobar pneumonia and bacteremia due to *Pneumococcus* type 1. The blood culture showed 260 colonies per cubic centimeter. Ketosis was mild and was cleared in six hours, only 75 units of insulin being used with oral and intravenous glucose. However, occasional traces of acetone reappeared until death. Despite the use of sulfadiazine and 200,000 units of type 1 antipneumococcus serum, the blood culture on the third hospital day showed 250 colonies per cubic centimeter and there was clinical evidence of spread of the pneumonic process. The patient died on the fourth day in the hospital, and autopsy showed complete consolidation of the right lower and right middle lobes, nearly complete consolidation of the right upper lobe, and patchy involvement of the left lung. In addition there were Laënnec's cirrhosis of the liver, with splenomegaly and subarachnoid hemorrhage.

CASE 5.—A woman aged 77 was admitted with fracture of the neck of the femur and diabetic acidosis. She was drowsy on admission, and ketosis was cleared in fourteen hours by means of 175 units of insulin and oral and intravenous glucose. There was no ketosis in the eight days prior to death, which was unexplained even after autopsy. The findings at autopsy were fracture of the neck of the femur, generalized atherosclerosis, nephrosclerosis, slight hyperplasia of the thyroid gland and slight bronchopneumonia.

CASE 6.—A woman aged 53 was admitted with lobar pneumonia of about seven days' duration, then involving almost all of the right lung. She was alert on admission but showed a heavy ketonuria. She received 90 units of insulin, 1,000 cc. of 10 per cent glucose in saline solution intravenously, plus oral glucose, but remained in ketosis until death two hours later in pulmonary edema.

CASE 7.—A diabetic woman aged 50 was admitted for study of insulin resistance. While in another hospital she had continued to show acetone and glucose in the urine even while receiving 400 units of insulin per day. An insulin tolerance test at that time had shown no response of the blood sugar to 50 units of regular insulin. On admission to our hospital she was alert and in mild ketosis, which cleared in fifteen hours on oral feeding and 625 units of insulin. On her fifth day in the hospital she again had asymptomatic acidosis, which cleared in twelve hours with 430 units of insulin, oral glucose and intravenous glucose. She was then free of ketosis until the tenth day in the hospital, after which progressively severe acidosis developed and she died in coma three days later. The administration of insulin was complicated by the development of local inflammation at the sites of injection; much of her insulin was given intravenously, but it was not more effective by this route. In the last twenty-four hours she received 1,310 units of insulin and 400 Gm. of glucose intravenously. Autopsy revealed no other cause of death. The patient's serum was shown to protect mice against convulsive and fatal doses of insulin.

Of these 7 fatal cases, only 2 remained in ketosis until the time of death. The others were freed from ketosis from one to eight days before death. Three of the patients were never drowsy or comatose. In 6 cases death was directly due to a highly fatal associated disease, not to diabetic acidosis, and in 4 of these our conclusions were substantiated by postmortem examination. In 1 of these cases (case 3) the fatal dissemination of a staphylococcal infection occurred after delay in the vigorous treatment of acidosis. This patient was transferred to our service in a moribund condition seven hours before death. In the seventh case the cause of death was diabetic coma, and it was established that this patient had specific neutralizing antibodies for insulin. We conclude that the crude mortality rate in this series is 7 per cent and that the mortality rate from diabetic acidosis is 1 per cent.

COMMENT

These results of therapy are not presented for purposes of comparison with those obtained at other hospitals where different methods of treatment are used. Such comparisons are not valid because of the many factors which determine the prognosis in the individual case. These factors have been exhaustively studied and discussed by Rabinowitch,⁴ and the more important ones from our experience are (a) the chronological and physiologic age of the patient, (b) the presence of associated diseases of serious import and (c) the severity of diabetic acidosis.

In 819 cases from four separate clinics, Rabinowitch⁴ found a regular increase in mortality rate with advancing age. In patients under 20 years of age the mortality rate was 5.1 per cent. About one third of the patients were over 40 years of age, and in these the mortality rate was 48.5 per cent. One third of our patients were 40 years of age or over, and all of the fatal cases were in this age group.

The mortality rate may be expected to be higher when to the risk of death from diabetic acidosis is added the risk of death from some other dangerous disease. In almost all reported series of cases of diabetic acidosis the mortality in complicated cases far exceeds that in uncomplicated ones. Indeed, there should be almost no mortality from uncomplicated diabetic acidosis under present day management. All but 1 of our fatal cases were complicated by another highly fatal disease which appeared on good clinical or pathologic grounds to be the major cause of death.

The severity of diabetic acidosis is estimated in some clinics largely by the state of consciousness of the patient, in others largely by the carbon dioxide combining power of the plasma. Rabinowitch⁴ has clearcut evidence on the relative prognostic value of these indexes. There was a direct relationship in his 125 patients between the degree of unconsciousness and the mortality rate. But in 713 collected cases there was no relationship between the level of the carbon dioxide combining power and the mortality rate. The highest mortality rate, in fact, occurred in patients with a carbon dioxide combining power above 25 volumes per cent! It has therefore seemed better to rely on the state of consciousness of the patient as the more correct and convenient index of the degree of ketoacidosis.

Although this series contains an average proportion of elderly patients and numerous instances of serious associated diseases, only a minority of our patients had serious disturbances of the sensorium.⁵ It may be argued that our method would appear less successful if we had had more comatose patients. Yet the conscious and the unconscious patients in this series were handled with equal ease, and the difficulties encountered were those of complicating conditions rather than those of intractable ketosis. In our hands this method of therapy has produced results as good as those achieved by other methods in current use. Before recommending it for general use, we would ask (a) Is it rational? (b) Is it practical, convenient and safe?

A patient in diabetic acidosis has invariably lost in his urine during the preceding days large amounts of water, sodium and glucose. This has been associated with a relative insufficiency of insulin. Particularly when nausea and vomiting are present, these losses

5. This is probably due in part to the fact that our hospital does not maintain an ambulance service. Hence most patients who are found in an unconscious state in our neighborhood are taken to city hospitals.

are not compensated by increased intake. The loss of sodium and water from the extracellular fluid is adjusted by transfer of water and potassium ion from the intracellular fluid. The loss of glucose is compensated by breakdown of liver glycogen, by gluconeogenesis from protein and by substituting fat for carbohydrate as a primary source of energy. Fat is burned for energy after being first broken down by the liver into ketone bodies. All of these processes are efficient only within limits, and, as Stadie⁶ and Mirsky⁷ have shown, when the rate of production of ketones by the liver exceeds the maximal rate of utilization of ketones by the tissues, ketones accumulate in the blood, combine with fixed base, and produce acidosis and ketonuria. The fundamental disturbance in diabetic acidosis is a depletion of water, sodium and glucose in association with a relative insufficiency of insulin.

There is general agreement that the most important step in the therapy of acidosis is the use of large quantities of insulin, and to this we subscribe. There is likewise general recognition of the need for restoring water and sodium ion, and in all clinics the patients receive water and sodium chloride, by vein if necessary. Sodium chloride is useful for relieving acidosis only if the kidney is capable of excreting the chloride in combination with ammonium ion, the sodium being retained as base. If the kidney is insufficient, most will agree that it is better to supply sodium as sodium lactate or sodium bicarbonate.

There has been disagreement concerning the use of glucose in the treatment of diabetic acidosis and diabetic coma. The state of depletion of carbohydrate in the body in diabetic coma has not generally been recognized because the blood, the only tissue tested under such circumstances, always shows an excessive concentration of sugar. That there is truly a state of depletion of carbohydrate in the body in coma is attested by the figures of Soskin,⁸ although these figures are contested by Root.² The technical difficulties of obtaining accurate analyses for glycogen on human patients are almost insuperable, and, rather than rely on data of questionable accuracy to determine whether the body is depleted of sugar, we have chosen to recognize the simple fact that there is an extra loss of carbohydrate from the body with unchanged or with diminished intake. In other words, the body is in negative carbohydrate balance.

It has been alleged by some writers that glucose "neutralizes" the action of insulin in the treatment of diabetic acidosis. This thesis has been supported almost entirely by reports of cases in which death has followed the use of glucose in the treatment of ketosis. In these cases it has been impossible to establish a clear relation of cause and effect. Let us inquire how this thesis fits in with what is known of the physiology of diabetic acidosis and of the actions of insulin:

The central problem in the relief of diabetic acidosis is to suppress the formation of ketone bodies in the liver. This is probably accomplished both by stimulating carbohydrate oxidation and by inducing the accumulation of glycogen in the liver. It is well known that insulin favors the accumulation of liver glycogen, and this is thought to be due to an inhibition of gly-

cogenolysis. Banting and his associates⁹ demonstrated that in fasting animals the hyperglycemia which follows the administration of epinephrine is prevented by insulin. Does glucose oppose the accumulation of liver glycogen in the diabetic organism? It does not. Increases of liver glycogen in diabetic animals have been obtained by Major and Mann¹⁰ and by Bodo and his associates¹¹ by infusions of glucose without the use of insulin. Mirsky⁷ has shown that diabetic patients in ketosis, either deprived of insulin or receiving suboptimal doses of insulin, exhibit diminished ketonuria and greater retention of carbohydrate when the intake of carbohydrate is greatly increased. In their effects on the level of liver glycogen, glucose and insulin are not antagonists. It seems more logical to regard them as substrate and enzyme in the same chemical reaction. This is in line with the findings of Macleod,¹² who studied the effects of insulin on diabetic animals with various levels of glucose intake, and concluded that:

The action of insulin on glucose metabolism no doubt proceeds according to the same general laws as govern enzyme action, namely that the amount of substrate which is acted on is not a linear function of the amount of enzyme but is relatively much greater when there is a large excess of substrate compared with the amount of enzyme. This latter condition is fulfilled when small amounts of insulin are given, or when, with larger amounts, the intake of sugar is increased.

Campbell, in the clinical section of the same paper, put this into practical terms. Speaking of the treatment of diabetic acidosis,

It has been the custom in Toronto [he said] to use 1 gram of glucose or other carbohydrate for each unit of insulin.

Indeed, the only known antagonism of glucose and insulin in diabetic individuals is in relation to the level of blood sugar. How unimportant a normal level of blood sugar is in recovery from diabetic acidosis is indicated by the fact that almost every one of our cases was cleared of acidosis while having a 4 plus glycosuria.

We differ from some other students of this problem in the degree of emphasis we place on the determination of the blood sugar and the carbon dioxide combining power in gauging the severity of acidosis and the progress of therapy. We have already indicated of how little value is the carbon dioxide combining power in determining the prognosis. We do not deny that a well run determination by an experienced technician is an accurate index of the severity of acidosis at the time it is taken, but though it may outweigh in accuracy the impression one gains from observing the respirations and the state of consciousness of the patient, this advantage is overcome by the delay in receiving the report. We have found that the result of such a determination is not available until from one to three hours later, and in many instances it is then only of academic interest. The determination of blood sugar is of no value for guiding therapy when glucose is administered as a part of the treatment. Our policy with respect to the use of blood chemical determinations is to use them when it is convenient to do so and to regard them as supplementary aids but almost never to perform them as emergency procedures.

The need for laboratory aids in estimating the severity of acidosis is further minimized in our method by the fact that we do not individualize the dosage of insulin but instead treat each patient with large amounts of insulin until ketosis is cleared. The individual dose of insulin given is small (25 units) but it is repeated every half hour. Thus it is intended that the patient receive in a period of six hours 300 units of insulin, a total dosage which is similar to that given in most clinics over an equal period of time. We believe this practice is effective because patients with all degrees of acidosis have responded equally well, and the only patient who failed to respond was one who was shown to be insulin resistant. We believe it is safe because we simultaneously administer glucose, and this has prevented the occurrence of hypoglycemia. A further danger of too vigorous treatment of acidosis has recently been suggested by Root, who points to the possibility of overloading the liver cells with glycogen. This hypothesis has been based, as far as we know, entirely on histologic studies of the liver. Such studies are not noted for their accuracy. Ketone production in the liver is probably suppressed at a time when the concentration of glycogen in the liver is still far below normal. Then when the ketone bodies disappear from the urine the dosages of insulin and glucose are reduced. In these circumstances it seems unlikely that there is danger of damaging the liver by excessive deposition of glycogen.

In most clinics it is the rule to administer large doses of insulin at a time, yet there are hardly two clinics that have the same concept of optimal dosage. The maximal rate of utilization of insulin is not known, and all routines for its use have been empirically constructed. In our plan of therapy, small doses of insulin are given and repeated frequently. We think that such a course is more efficient, because it has been known since the original work of Banting and his associates that the law of diminishing returns applies to insulin: Small doses metabolize more carbohydrate per unit than do large doses. We think that this procedure is safer, because there is less likelihood of severe hypoglycemia from the delayed effect of large doses of insulin.

We are aware that as good results as ours in the treatment of diabetic acidosis have been achieved by workers with long experience in this field, using a method which forbids the use of exogenous glucose, which demands control of the progress of the patient by frequent chemical testing of the blood and which relies on the empirical selection of proper doses of insulin. We are inclined to regard these good results as due in large part to the great experience of these physicians, for we know of other groups with equal medical wisdom and conscientiousness who have failed to achieve equal results by the same method. Our method has not been used extensively by specialists in diabetes mellitus; the results reported here were achieved by interns. We are convinced that this method is simpler. It allows the treatment of all cases of diabetic acidosis with equally large individual doses of insulin, without fear of insulin reactions. It does not require the use of time consuming laboratory tests. It does not require the constant attendance of a diabetes specialist to select the appropriate dose of insulin. In other words, this method can be applied by any physician who has facilities for testing the urine and who understands the basic functional pathology of diabetic acidosis.

SUMMARY

1. A method of treatment of diabetic acidosis has been adopted in which are used small and frequently repeated doses of insulin and replacement of water, sodium chloride and glucose by mouth or by vein.

2. The course of therapy is guided by clinical signs and qualitative analysis of the urine for sugar and acetone bodies.

3. In the great majority of cases at our institution, treatment is given by the house staff, guided only by the resident physician.

4. Among 99 cases of diabetic acidosis and diabetic coma so treated during the past five years there were 7 deaths, only 1 of which was due to diabetic acidosis per se. In that patient there was proved insulin resistance of a high order.

CONCLUSION

Our experience indicates that patients with diabetic acidosis or diabetic coma can be successfully treated with small, standard and frequently repeated doses of insulin, that the administration of glucose in this disorder is beneficial and not harmful, that it is not necessary to follow the blood sugar and carbon dioxide combining power as guides to therapy, and that with such a simple method the constant attendance of specialists in diabetes mellitus is, in all but rare instances, unnecessary.

Clinical Notes, Suggestions and New Instruments

BUERGER'S DISEASE IN A BOY OF SIXTEEN YEARS

CAPTAIN EDISON D. FISHER
MEDICAL CORPS, ARMY OF THE UNITED STATES

Thromboangiitis obliterans usually affects males between the ages of 20 and 50 years. Horton¹ reported a series of 984 cases seen over a period of thirty years at the Mayo Clinic in which their youngest patient was 17 years of age. A search indicates that the subject of the present report is the youngest in the English literature. The disease developed while he was 15 and was well advanced when we saw him shortly after his sixteenth birthday.

REPORT OF CASE

J. D. H., a high school student aged 16, presented himself to the outpatient department of the Mason Memorial Hospital at Murray, Ky., on Dec. 13, 1938 because of pain and tenderness in his right foot. Four months previously he had observed that the ball of this foot was tender. In the course of time this tenderness was replaced by numbness, then a burning sensation and finally severe pain, especially in the fourth and fifth toes. The right calf was sore and cramped when he walked. The situation became progressively worse, so that on December 26 he was admitted to the hospital for treatment. He arrived about midnight complaining of excruciating pain in his right foot, especially the fifth toe.

His ancestors, who had been Americans for several generations, were of Scotch-Irish extraction with nothing of special significance in the family history. He was a normal breast fed infant who had passed through a normal childhood with no incidents of clinical interest other than uncomplicated measles, whooping cough and scarlet fever. His adolescence had been uneventful until the onset of the present disability. He had smoked cigarettes for about two years and at the time of admission was using about twenty cigarettes a day.

Physically he was rather slender and evidently rapidly growing, and his general development was about normal. He did not appear acutely ill but evidently was suffering much pain.

1. Horton, B. T.: The Outlook in Thromboangiitis Obliterans. *J. A. M. A.* 111: 2184-2189 (Dec. 10) 1938.

His temperature was 98 F., pulse rate 84, respiratory rate 16 and blood pressure 126/74. His height was 68 inches (173 cm.) and weight 122 pounds (55 Kg.). A rather extensive chronic acne was present on the face and upper part of the chest. No disease or abnormality of the heart or lungs was found. The upper extremities were normal with no disturbances of blood supply, trophic changes or signs of autonomic imbalance.

No other significant departures from normal were present aside from the findings in the right lower extremity. The right foot was cold, mottled and cyanotic. A gangrenous appearing ulcer on the fifth toe extended from the base of the nail to the medial aspect of the toe. The ball of the foot and the fourth and fifth toes were very tender and painful. Pulsations were absent in the dorsalis pedis and posterior tibial arteries and reduced in volume in the popliteal artery. When the foot was elevated it became blanched, when dependent it was very cyanotic and when on the horizontal plane its color was a mottled cyanosis. The right leg below the midcalf was constantly colder than the left. None of the abnormal findings of the right lower extremity were present on the left.

Mentally he was of average intelligence, well adjusted and emotionally stable. Neurologic findings were within normal limits.

The laboratory findings were not striking. Blood examination revealed a normal red cell count, hemoglobin, leukocyte and differential count, blood sugar and nonprotein nitrogen. A mild leukocytosis appeared for a few days when the toe ulcers were the most extensive. Blood sodium chloride was 454 mg. and the Wassermann reaction was negative. The urine was essentially normal.

On the second hospital day he was given a procaine spinal anesthetic as a diagnostic measure. Anesthesia was produced in both lower extremities. The left leg and foot became pink and warm and the dorsalis pedis and posterior tibial pulsations were voluminous, but very little change, if any, was observed in the right foot. It remained cold and cyanotic and its arteries pulseless. These findings, considered in the light of the history and physical findings, substantiated a diagnosis of thromboangiitis obliterans.

Treatment consisted of Buerger's exercises twice a day, contrast leg baths three times a day, local dressings of butesin picrate to the ulcerated toes and analgesics as needed. A heating cradle at about 95 F. was tried for a few hours, but it so increased the pain that it was removed. All tobacco was discontinued.

During the first ten days of hospitalization all of his symptoms became progressively worse. The ulcer on the fifth toe became larger, and a smaller one appeared on the adjacent fourth toe. The pain became so severe that opiates were required and the patient requested that his toes be amputated. On the eleventh day, apparently without reason, the foot became quite comfortable and the ulcers began to heal. Evidently sufficient collateral circulation had developed to permit rapid and uninterrupted healing. Eighteen days later, when the patient was discharged from the hospital, the ulcers were healed and the foot was comfortable.

On returning home the patient was instructed to take extra good care of his feet, to continue with Buerger's exercises and to return periodically for a checkup. Later he returned to high school and drove a truck during vacations. Sustained brisk walking caused mild intermittent claudication, but he had no more serious difficulty. The arterial pulsations in the right foot remained absent to palpation. Early in 1941 he was accepted by the Navy and according to reports late in 1943 he was still carrying on successfully.

SUMMARY AND COMMENT

1. A case of Buerger's disease had its onset at the age of 15 years.
2. Severe disease of the right foot improved rapidly with Buerger's exercises, contrast leg baths and discontinuance of all tobacco. Nearly four years later the patient had no relapses. It is difficult to evaluate the part treatment played in the unexpected rapid improvement in this patient.
3. The interest and significance of this case report is that Buerger's disease may develop so early in life.

TREATMENT OF SEVERE NECROTIC LESIONS HIGHER PENICILLIN DOSAGE WITH SIMULTANEOUS REGIONAL SYMPATHETIC BLOCK

MEYER NAIDE, M.D., AND ANN SAYEN, PHILADELPHIA

Gas gangrene has been reported in fairly large numbers in this war. Forty-four cases with 13 deaths and 8 additional amputations in recovered patients were reported by MacLennon¹ in British army casualties in the North African campaign, an incidence of between 6 and 7 per thousand wounded. Twenty cases were seen by Power² in 6,000 casualties in the fighting in Normandy. In 16 of these patients there were 10 amputations and 2 deaths.

Despite increase in the potency of antisera and chemotherapy, local and systemic, results of treatment of gas gangrene are not much better than they were twenty-five years ago.¹ A consideration of the problem makes it obvious that the reason for failure is twofold: There is an inadequacy in blood supply to necrotic tissue and therefore the amount of penicillin reaching this tissue at the usual blood level is completely inadequate. This may explain the failure of chemotherapy in some patients and the present high mortality and amputation rate. Nowhere in the literature have we been able to find a suggestion that much larger doses of penicillin are required when there is reduced blood flow. Power² as recently as May 12, 1945 has gone so far as to state that "early reports on penicillin would indicate that it is powerless to stem the progress of gas gangrene."

That gas gangrene occurs in ischemic, necrotic tissue is recognized.² That chemotherapy of ischemic tissue is a special problem in itself has not been recognized.

The importance of this problem was brought to our attention by the death of 1 patient with gas gangrene in an ischemic extremity treated with the recommended dose of 100,000 units of penicillin daily, intramuscularly and the recovery without amputation of another patient with a similar infection in an ischemic extremity, but treated with 600,000 units of penicillin daily, intravenously and with two periods of continuous caudal anesthesia for prolonged complete vasodilatation. This led us to the opinion that penicillin is being used in completely inadequate dosage in severe infections in ischemic tissue.

Following is the report of a case of gas gangrene in an ischemic extremity finally treated by us with massive doses of penicillin and caudal anesthesia:

A woman aged 50 was admitted to the University Hospital on April 24, 1945 with a history of diabetes mellitus for seven years. In March 1945, one month before admission to the hospital, she refused to take her daily dose of 30 units of protamine zinc insulin. One week later she noticed that several toes were black on both feet. A week before admission to the hospital she developed fever. The significant physical findings on admission were a temperature of 102 F., pulse rate of 120, a systolic murmur at the apex, foul-smelling gangrene of the second toe on the right foot and the second and third toes on the left foot, with cellulitis of both feet. The dorsalis pedis pulses were present but the posterior tibials were absent. Cataracts had been removed bilaterally. A note was made on the day of admission that bilateral amputation would probably be necessary to control the infection. The white blood cell count was 14,000, the blood sugar 250 mg. per hundred cubic centimeters. The urine was positive for sugar and acetone. Carbon dioxide was 41 volumes per cent.

The patient was started on 100,000 units of penicillin intramuscularly on the day of admission, April 24. On April 27 x-rays showed a large quantity of gas in the soft tissues of the right foot and to a lesser extent in the left, with either osteomyelitis or demineralization of the right second and the left second and third toes. That day the affected toes were amputated and anti-gas serum and tetanus antitoxin were given. The diabetes mellitus was controlled with diet and 80 units of

From the Peripheral Vascular Section of the Edward B. Robinson Foundation, Medical Clinic, Hospital of the University of Pennsylvania. The cost of the penicillin used in this work was defrayed in part by the Donney Fund for Needy Patients.

2. Power, R. W.: Gas Gangrene with Special Reference to Vascularization of Muscles, *Brit. M. J.* 1: 656 (May 12) 1945.

regular insulin. The 100,000 units of penicillin intramuscularly was continued daily. A culture was made on April 27 which disclosed hemolytic streptococci and staphylococci but no clostridia. A smear on April 30 disclosed gram positive rods, and there was gas on palpation in the left foot. An additional incision was made that day for drainage. The penicillin was increased to 200,000 units intramuscularly on April 30. Despite this the temperature remained elevated, the patient was toxic and the lesions were foul. As a patient had been seen in March 1945 with severe ischemia and gas gangrene who died after treatment with 100,000 units of penicillin intramuscularly daily and local surgery, it was suggested that 600,000 units of penicillin be given daily, intravenously. This was done and within twenty-four hours the temperature dropped to a lower level, remaining below 100 F. The patient received anti-gas serum twice more for a total of 60,000 units (40,000 intravenously and 20,000 intramuscularly). On May 11 and 12 continuous caudal anesthesia was instituted for periods of six hours in an effort to increase blood flow through maximal vasodilatation and thus increase the amount of penicillin reaching the infection in the ischemic tissue. The presence of pain and anxiety suggested the possibility that peripheral vasoconstriction was reducing the amount of penicillin reaching the infection. The temperature level dropped within twenty-four hours and it remained below 99 F. from May 11 to 20 and was normal thereafter. The right foot healed completely. The left foot is much improved, although additional surgery may still be necessary.

One other case pertinent to the problem is worth mentioning briefly: A man aged 65 came into the hospital with moist necrosis of the tip of the right third toe. An x-ray showed osteomyelitis of the distal phalanx of this toe. Although the patient had occlusion of the right popliteal artery, he did not complain of claudication, the foot was warm, there was no severe pain and it was evident that he had established an adequate collateral circulation. It was decided to use 300,000 units of penicillin daily, intramuscularly. After five days of treatment the necrotic tip became dry, pain subsided completely and the patient was discharged after ten days in the hospital. The feature that permitted successful treatment of this patient with penicillin intramuscularly was evidence of a good collateral circulation and absence of severe pain despite arterial occlusion in the extremity. There is more adequate blood flow to the toes of a foot with arterial occlusion where an adequate collateral circulation has been established and where this is no vasospasm than there is in the toes of some feet with a patent arterial system and reflex vasospasm due to pain, trauma or cold.

COMMENT

Failure to recognize that ordinary doses of penicillin may be inadequate in treating severe infections in ischemic tissue may be a factor in the high mortality and amputation rate in gas gangrene. Kunkel and Stead³ found that an ischemic foot may have from one third to one tenth of the normal blood supply. It would therefore seem obvious that penicillin dosage must be increased correspondingly, since only a small fraction will reach an ischemic lesion. Fortunately one can do this with penicillin, whereas this is not equally possible with the sulfonamides, which are more toxic in huge doses. Furthermore the intravenous route, using the high doses, is effective in maintaining such a high concentration that even the smaller amount of blood reaching ischemic tissue may have sufficient penicillin to be effective.

The use of massive doses of therapeutic agents in treating symptoms of ischemia is not new. In 1939 one of us⁴ pointed out that the problem in arterial occlusive disease is basically that of a block in transportation. It was found that ischemic neuritis could be relieved in some patients by the use of massive doses of thiamine hydrochloride intravenously (100 mg. daily), whereas smaller doses intravenously or subcutaneously were of no value.

Vasodilation methods such as continuous caudal anesthesia for six or eight hours will increase blood flow and thus the amount of effective penicillin. It must be remembered that ischemia of

wounds is the result not only of vascular injury but also of reflex spasm of collateral vessels in response to pain and anxiety.

The importance of early surgical removal of necrotic tissue in patients with gas gangrene has been adequately stressed by others. The use of penicillin locally is also indicated, though it is not sufficient in itself. MacLennan¹ and others have pointed out the importance of using large quantities of antisera intravenously, if possible, his patients averaging 90,000 to 100,000 units.

In 28 of MacLennan's 44 cases there was severe trauma to a major artery. Power² has stressed the vascular factor present in all military wounds with gas gangrene seen by him. In 9 of the 16 patients seen by him there was injury to the popliteal artery; in every case amputation had to be performed. He points out that vasodilatation should be encouraged by hot drinks, heat to the uninjured limbs and alcohol. Smoking should be prohibited to avoid reflex vasoconstriction. Heat is contraindicated. Increased penicillin and vasodilator therapy is indicated despite failure to find gas-forming organisms. In only half of MacLennan's cases of gas gangrene were gas-forming organisms found.

CONCLUSIONS

The present recommended dose of penicillin in gas gangrene is inadequate. The reduced blood supply does not permit an effective amount of penicillin to reach ischemic tissue at the usual penicillin blood level.

It is therefore imperative in these lesions to use much larger doses of penicillin, preferably intravenously, to increase greatly the level of penicillin in the blood reaching the necrotic tissue.

It is also important to increase blood flow simultaneously by regional sympathetic ganglion block.

These methods are to be used in conjunction with present adequate local surgical management and with repeated doses of antitoxin intravenously, if possible.

Council on Pharmacy and Chemistry

REPORT OF THE COUNCIL

The following statement has been authorized for publication by the Council.

AUSTIN SMITH, M.D., Secretary.

INFORMATION ON NEW DRUGS

The Council office receives many inquiries concerning the status of drugs newly introduced in commerce and those which are still in the stage of experimental investigation. On the basis of the information which is available in the Council files and that received from consultants to whom the Council may write, these inquiries are answered. However, to give the best information service it is necessary to have the cooperation of those who are responsible for the introduction and distribution of new drugs, and it is important that such information is received as promptly as possible. Manufacturers and others are urged to keep the Council office informed concerning new developments relating to products in which they are interested. At the same time they should of course notify the Council office if there is any restriction on the information, as such restriction will be observed. Ordinarily it is necessary to transmit a digest of the information only when replying to inquiries, but it should be understood that the Council must be free to comment on the supplied data if the occasion arises for such comment; while these comments would aim to be unbiased, they may on occasion be adverse because, for example, of the lack of evidence to support the claims or implied uses. Nevertheless, the end result would be more complete information and a better understanding of the problems involved. Every one participating in the accumulation of this information would benefit. Manufacturers are invited to keep the Council informed; at the same time members of the medical profession and others with similar interests are also invited to make use of the information available in the Council files. Inquiry may be directed simply to the Secretary of the Council on Pharmacy and Chemistry, in care of the American Medical Association, 535 North Dearborn Street, Chicago 10.

Council on Foods and Nutrition

The Council on Foods and Nutrition has authorized publication of the following report.

GEORGE K. ANDERSON, M.D., *Secretary.*

THE EFFECT OF COCOA ON THE UTILIZATION OF DIETARY CALCIUM

H. H. MITCHELL, PH.D.

AND

JANICE M. SMITH, PH.D.

URBANA, ILL.

Cocoa is one of many foods commonly used in American diets that contains moderate amounts of oxalic acid, i. e. 0.5 to 0.6 per cent. On a similar moisture basis, cocoa contains about the same content of oxalic acid¹ as wax beans and gooseberries, slightly more than green beans, carrots and the peelings of citrus fruit, but slightly less than celery stalks. The oxalic acid of foods is capable of forming an extremely insoluble salt with dietary calcium, and for this reason it may impair the utilization of the calcium of foods in the body. Since cocoa and chocolate are used extensively in milk and ice cream, the possibility that the calcium of these dairy products would thus be rendered less available in digestion and metabolism induced Mueller and Cooney of the Massachusetts State College to study the problem with growing rats. The results of this investigation were published about two years ago² and have attracted wide interest among nutritionists³ and particularly within the dairy industry, since chocolate flavors in milk and ice cream have been introduced evidently in response to a consumer demand and may be presumed to increase the consumption of these excellent foods.

The experiments of Mueller and Cooney were designed to compare the retentions of calcium in the bodies of growing rats receiving a diet containing 0.554 per cent of calcium and 0.472 per cent of phosphorus derived from whole milk powder when this diet was fed alone and when it was supplemented with cocoa in the proportion of 0.84 part of the basal diet to 0.16 part of cocoa. Twenty-one pairs of rats were used in addition to 21 litter-mate control rats killed and analyzed at the beginning of the experiment to permit an estimate of the initial stores of calcium. Within each pair of rats the consumption of the basal diet was equalized, while 1 of the pair received the cocoa powder in addition. After five weeks of feeding the rats were killed and analyzed for calcium and phosphorus.

The results of this well conceived and well executed experiment were clearcut in their significance as revealed by statistical analysis.⁴ The rats fed the cocoa supplement, although receiving 19 per cent more dry food, 6 per cent more calcium and 30 per cent more phosphorus than the rats on the basal diet only, grew only 89 per cent as fast and deposited in their bodies only 76 per cent as much calcium and 80 per cent as much phosphorus. The effect of the cocoa supplement

on growth had been previously⁵ shown by Mueller⁴ to be traceable probably to its content of tannic substances. The primary effect on mineral utilization was probably on calcium, since (1) calcium was presumably a limiting factor in the diet, (2) calcium limitation will restrict phosphorus utilization because the two minerals are so largely utilized together as a calcium phosphate in bone formation, and (3) the depression of phosphorus retention by cocoa was so nearly the same as that of calcium retention. However, the oxalic acid content of the cocoa could account for only about one third of the observed depression in calcium retention. No clue to the residual causes of this depression was afforded by the data of the experiment or the discussion of them by the authors. It should be noted that the ratio of milk solids to cocoa in the diets of this experiment was about 3.3 to 1, while in chocolate milk it is ordinarily about 13 to 1.

The cocoa that Mueller and Cooney used was a low cost American process cocoa⁵ containing 11.23 per cent fat and 5.25 per cent fiber. Cocos of this description are common at times on the market, being used in the manufacture of bakery goods and for low cost chocolate syrups and confections, though there seems to be a considerable sale of such products for domestic use by certain retail stores throughout the country.

Similar experiments were made on growing rats at the University of Illinois, essentially the same technic being used as that employed by Mueller and Cooney, but three different kinds of cocoa being studied, i. e. the low cost brand used by the Massachusetts investigators (cocoa A), an American process breakfast cocoa (cocoa B) and a Dutch process cocoa (cocoa C). The latter two cocos were medium cost cocos containing 22 to 24 per cent of fat and 3.6 to 3.9 per cent of fiber. In the Illinois experiments the cocos were incorporated into the basal diets at the expense of sugar instead of being added to the diets, and all diets were equalized in fat content. Nine and twelve pairs of rats were used in each of two tests, and pair mates received equal amounts of their respective diets. However, the body weight gains of pair mates were equalized by additions of sugar to the diet of the laggard rat, which was generally the rat receiving cocoa. The experiments were terminated after four to nine weeks of feeding, depending on the rate of growth in each pair, and the carcasses were analyzed for calcium and, in one test, for phosphorus also.

The amount of extra sugar required to maintain equal gains in the cocoa and noncocoa rats, in percentage of the basal food consumed, averaged 18.3 for cocoa A, 6.1 for cocoa B and 4.6 for cocoa C. The difference in this respect between the low cost cocoa A and the higher cost cocos is highly significant statistically. The calcium retentions of the rats on the three cocoa diets, expressed as percentages of intakes of calcium, showed depressions of 27.7, 14.8 and 18.4 per cent as compared with the control rats receiving no cocoa. Again the detrimental effect of the low cost cocoa A exceeded statistically the effect of the two medium cost cocos B and C, which were not statistically distinguishable in this respect. The three cocos contained essentially the same contents of oxalic acid, 0.55, 0.50 and 0.51 per cent respectively. The depressing effect of the B and C (medium cost) cocos on calcium retention can be entirely accounted for by their contents of oxalic acid, but as in the work of Mueller and Cooney, only about

one third of the depression in calcium retention induced by the low cost cocoa A can be so explained.

The chemical (and physical) analysis of the three cocoas does not afford any direct explanation for the more harmful effect of cocoa A as compared with cocoas B and C. Besides the chemical data already given, our analysis indicates the percentages given in the accompanying table.

The higher proportion of cacao shell⁶ and possibly the lower proportion of fat⁷ may be involved in the greater detrimental effect of the low cost cocoa A, with reference both to growth and to calcium utilization.

The experiments on rats at the University of Illinois were carried out in conjunction with a series of experiments⁸ on 7 women students (ranging in age from 18 to 22 years), extending over fifty-one four day calcium balance periods. A low calcium basal diet containing an average of 225 mg. of calcium per day and no cocoa was fed alone in thirteen four day periods, supplemented with cocoa in six periods and supplemented with dairy products (milk and ice cream) and cocoa in thirty-two periods. In the latter periods adjustments were made in the basal diet at the expense of low calcium foods to maintain a fairly constant intake of protein and of calories. The cocoa used in these experiments was an American process cocoa of medium cost, manufactured by the same firm and similar in composition to the cocoa B in the rat studies, except for a somewhat lower fat content,

Analysis of Three Cocoas

	Tannic Sub- stances, %	Theobrom- ine, %	Mois- ture, %	Proportion Not Passing Through a 140 Mesh Sieve, %
Cocoa A.....	11.80	2.10	5.73	11.51
Cocoa B.....	10.57	1.79	4.70	1.12
Cocoa C.....	6.62	1.44	5.20	0.87

20.22 per cent. This cocoa represents approximately the quality normally used in making dairy syrups for the manufacture of chocolate milk and ice cream. In the supplemented diets the calcium intake was raised to about 700 mg. daily, of which dairy products, milk or milk and ice cream, supplied about 71 per cent. The cocoa was added to the diets in amounts varying from 5.5 Gm.⁹ to 34.8 Gm. daily and, in the different diet periods, it was incorporated in milk alone, in ice cream, in cookies, in candy or in syrup. For each type of diet with reference to cocoa dosage and manner of incorporation in the foods, each subject during half of the period received cocoa and during the other half of the period received none. Hence, for each of the four diets, comparisons of calcium retention were possible between subjects and between periods on the same subject.

The results of the experiments on human subjects were essentially negative in their significance in the sense that no deleterious effects on calcium metabolism of this particular brand of cocoa in the amounts consumed were revealed. For all periods and subjects, the calcium balances on the cocoa diets averaged — 9.74 mg. per day and on the noncocoa diets — 12.37 mg. per day,

the difference being insignificant statistically. The calcium intakes on the cocoa and noncocoa diets averaged very nearly the same, 604 and 590 mg. per subject daily respectively. Among twenty-seven comparisons of calcium balances involving each subject on each diet, with and without cocoa, sixteen favored the cocoa diet and eleven the noncocoa. The deviation of 2.5 from the ideal outcome of 13.5 if random factors alone operated is somewhat less than the standard deviation of twenty-seven events, each of which, with equal probability, may result in either of two ways, i. e. $\sqrt{0.5 \times 0.5 \times 27} = 2.6$. Hence such a deviation may well have resulted from chance only. An application of the analysis of variance to each diet comparison confirmed the essentially negative significance of the data.

These negative results may mean that in human subjects the cocoa used has no effect on calcium utilization. On the other hand, they may mean that the method of study is not sufficiently sensitive to detect an effect of cocoa because of the variation among the data within diet periods and within subjects due to uncontrolled factors. A statistical analysis of this variation showed that for all four diet periods the variation was such that average differences of 116, 57, 145 and 25 mg. respectively in calcium balance per subject daily induced by a dietary factor such as cocoa would have been detected with a probability of 0.05. This means that the uncontrolled intraperiod and intragroup variation would be expected to produce an average difference in calcium balance of these magnitudes (or greater) only once in twenty trials. With the final low calcium diet, which was unsupplemented with cocoa for twelve days for each subject and supplemented with 21 Gm. of cocoa daily for an adjacent twelve day period, the uncontrolled variation was so much less than with that of the other diets that an average difference in calcium balance of only 25 mg. could have been detected with a probability of 0.05: Twenty-one Gm. of cocoa contains 105 mg. of oxalic acid, capable of combining with 46 mg. of calcium. On the other hand, 21 Gm. of cocoa itself contains 30 mg. of calcium, enough to combine with two thirds of the oxalic acid contained in it. In another diet period in which the critical difference in calcium balance detectable at the 5 per cent probability level was 57 mg., the daily cocoa supplement amounted to 1 ounce (28.35 Gm.) and contained 142 mg. of oxalic acid, sufficient to combine with 63 mg. of calcium. In this case the cocoa supplement contained 41 mg. of calcium, leaving an excess of oxalic acid sufficient to combine with only 22 mg. of calcium contained in the basal foods. These calculations illustrate the difficulty of detecting the effect of cocoa on calcium metabolism in the human being if the effect is due entirely to the oxalic acid contained in it.

Any discussion of the possible effect of cocoa on the utilization of dietary calcium in the human organism should consider the possibility that calcium oxalate is considerably more efficiently utilized in the human organism than in the body of the rat. The rat has been shown¹⁰ to be almost completely incapable of utilizing calcium oxalate or the calcium of spinach, a vegetable containing more than enough oxalic acid to combine with its content of calcium. That the human body utilizes the calcium of spinach to a considerable extent is indicated clearly by the experiments of

8. These experiments as well as the rat feeding experiments were aided by funds granted to the University of Illinois by the National Dairy Council on behalf of the chocolate industry and the International Association of Ice Cream Manufacturers.

9. The amount of cocoa contained in 400 cc of chocolate milk containing 1.4 per cent of cocoa. Incidentally this amount of cocoa, 5.5 Gm., approximates the average daily consumption in this country.

10. Fairbanks, B. W., and Mitchell, H. H.: The Availability of Calcium in Spinach, in Skim Milk and in Calcium Oxalate. *J. Nutrition* 16:79 (July) 1938.

McLaughlin¹¹ and of Fincke and Garrison.¹² The experiments of Bonner and others¹³ on children failed to detect an adverse effect on calcium utilization of 100 Gm. daily portions of canned spinach or of an amount of oxalic acid, 700 mg., contained in such portions. It is true that the calcium intake in these experiments, ranging from 800 to 1,300 mg. daily, was liberal for these subjects, but the oxalic acid doses used were capable of combining with over 300 mg. of calcium. Even so, the fecal excretion of calcium, which presumably include the calcium oxalate thus formed, was only inconsiderably increased by an average of 28 mg. daily in the spinach periods and of 42 mg. in the oxalic acid periods.

On other grounds also the effect on calcium retention of oxalic acid, or any other agent capable of immobilizing calcium in the alimentary canal, would be much greater in the rat than in the human being. The rat is able to utilize non-oxalate calcium to a much greater extent than is man, and hence the precipitation of a given weight of calcium in the intestine by oxalic acid has a much greater effect on the calcium economy of the body. In the Illinois experiments on rats the calcium intake was retained to the extent of 89 per cent on the average by the animals on noncocoa rations. Hence the immobilization of 100 mg. of dietary calcium by the oxalic acid of cocoa would be expected to depress calcium retention by 89 mg. However, in the experiments on women the sparing effect of dietary calcium on body calcium averaged about 19 per cent, in agreement with many other tests reported in the literature. In this case the immobilization of 100 mg. of dietary calcium by oxalic acid would reduce calcium retention by only 19 mg.

An interesting finding in the experiments on human subjects reported here in a preliminary way was that the tolerance limit for cocoa was about 1 ounce daily. Larger portions induced headache, nausea and impaired appetite. To consume the equivalent of 1 ounce of cocoa containing 20 per cent fat in the form of sweet chocolate prepared with the minimal proportion of chocolate liquor, 15 per cent,¹⁴ one would have to consume approximately 12 ounces. A detailed report of both the rat and the human experiments will be published elsewhere.

CONCLUSIONS

In the growing rat, two medium cost cocoas containing about 22 per cent of fat depressed the utilization of calcium in proportion to their content of oxalic acid. A low cost cocoa containing about 11 per cent fat and apparently appreciably more cacao shell depressed growth more than the higher grade cocoas and depressed calcium retention about twice as much as can be accounted for by its content of oxalic acid.

In adult human subjects, whether subsisting on a low calcium diet or on diets of borderline calcium adequacy, a medium cost cocoa in daily portions of 21 to 38 Gm., approximating the tolerance limit, was not shown to affect the calcium balance adversely.

However, if the effect of such cocoas on calcium utilization resides entirely in their content of oxalic acid, as the rat experiments indicate, it would not be expected

to be appreciable in human metabolism, because the oxalic acid content of cocoa is only moderate, i. e. 0.5 to 0.6 per cent, and the calcium in the cocoa itself is sufficient to combine with about two thirds of the oxalic acid. Furthermore, the immobilization of milk calcium in the digestive tract by the remaining third of the oxalic acid of cocoa, equivalent to 22 mg. of calcium for a 1 ounce portion of cocoa, would be expected to depress calcium retention by only one fifth of this amount (4 or 5 mg. of calcium), because of the poor utilization of calcium (19 per cent or so) by the adult human organism. Such a small depression in calcium retention is practically impossible to detect by the technic of the metabolism experiment with human subjects.

The effect of low cost, low fat (dry) cocoas, rather commonly used in this country at times, should be tested on human subjects with reference to tolerance and to calcium utilization, since with these cocoas other constituents than oxalic acid may depress the utilization of dietary calcium.

ACCEPTED FOODS

The following additional foods have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association for admission to Accepted Foods.

GEORGE K. ANDERSON, M.D., Secretary.

CANNED AND DRIED FRUITS AND FRUIT PRODUCTS (See Accepted Foods, 1939, p. 70).

Florida Citrus Cannery Cooperative, Lake Wales, Fla.

DONALD DUCK, PRICELESS BRAND AND SEALDWEET BRANDS CONCENTRATED ORANGE JUICE The freshly squeezed juice is concentrated under a high vacuum and then filled hot into cans, which are sealed, flash pasteurized at 200 F. and then held in 40 F. storage

Analysis (submitted by manufacturer).—Moisture 35.0%, total solids 65.0%, acid (as citric) 5.0%, invert sugar 25.0%, total sugar 50.0%, protein (N X 6.25) 4.3%, pectin 0.3%, volatile oil 0.0025%, ascorbic acid 215 mg., phosphorus 120 mg., potassium 1,600 mg., calcium 80 mg., magnesium 78 mg., manganese 0.14 mg., iron 0.1 mg., aluminum 0.3 mg. per hundred cubic centimeters, specific gravity 1.318

Calories—In the concentrate, 2½ per gram In the diluted product, ½ per gram

Vitamins—Ascorbic acid (titration method) in juice reconstituted with six volumes of water contains not less than 40 mg. per hundred cubic centimeters

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156)

Harold H. Clapp, Inc., Rochester, N. Y.

CLAPP'S JUNIOR FOODS PEARS, consisting of pears and sugar.

Analysis (submitted by manufacturer).—Total solids 16.27%, crude fiber 1.26%, protein (N X 6.25) 0.30%, ash, 0.23%, fat (ether extract) 0.05%, carbohydrate (by difference) 14.43%, phosphorus (P) 9.6 mg. per hundred grams, calcium (Ca) 8.7 mg. per hundred grams, iron (Fe) 0.7 mg. per hundred grams, copper (Cu) 0.11 mg. per hundred grams

Calories—16.7 per ounce; 0.59 per gram

Vitamins—Ascorbic acid 3.6 mg. per hundred grams, riboflavin 0.025 mg. per hundred grams

Heinz Company, Pittsburgh.

HEINZ STRAINED APRICOTS WITH OATMEAL contains fresh apricots, oat flour, sugar and water.

Analysis (submitted by manufacturer).—Total solids 25.79%, total sugar as sucrose 19.11%, acidity as citric 0.42%, protein (N X 6.25) 0.90%, fat (by acid hydrolysis) 0.28%, crude fiber 0.61%, ash 0.37%, salt 0, total carbohydrates other than crude fiber by difference 23.21%, calcium 10.0 mg. per hundred grams, phosphorus 22.0 mg. per hundred grams, iron 0.5 mg. per hundred grams, copper 0.11 mg. per hundred grams, lead 0.06 mg. per hundred grams (0.0042 grains per pound), arsenic 0

Calories—0.99 per gram, 28 per ounce

SATURDAY, NOVEMBER 24, 1945

THE NATIONAL HEALTH PROGRAM— THE PRESIDENT'S MESSAGE

In the Organization Section of this issue of THE JOURNAL appears the complete text of the message of President Harry S. Truman to the Congress, delivered on November 19. The text was received as THE JOURNAL was going to press. The President presents a five point program. The measures proposed by the Hill-Burton bill for increased funds for hospitals and health centers throughout the nation are covered by his first point. The American Medical Association has approved the principles of the Hill-Burton bill subject to safeguards which are in the text reported by the committee which conducted hearings on this measure.

The second recommendation of the President is for expanded maternal and child health services—essentially those proposed by the Pepper bill. It should be apparent that the passing of a nationwide compulsory sickness insurance bill ought to make unnecessary the kind of proposals included under the Pepper Maternal and Child Health measure.

The President urges increased funds for medical education to be given to public and nonprofit institutions for extending medical education and particularly for research in the fields of cancer and mental health. Obviously this proposal is duplicated to some extent by the proposals for the National Science Foundation. This proposal would place the federal government definitely in control of medical education throughout the United States through its ability to allocate funds to medical educational institutions.

The fourth proposal is for a nationwide system of compulsory sickness insurance to cover every man, woman and child in the United States and to care for the indigent through insurance policies purchased by local agencies for which they would be reimbursed in whole or in part by the federal government. The American Medical Association has opposed compul-

sory sickness insurance consistently for many years. The President reaffirms Senator Wagner's peculiar interpretation of the term socialized medicine by claiming that "this is not socialized medicine." The affirmation will not be convincing to the physicians of the United States who would be compelled to submit to politically controlled medicine should such a measure ever become the law of the nation.

Finally, the President urges compensation of workers for disability due to illness. The House of Delegates of the American Medical Association has approved such proposals in the past.

Fortunately the House of Delegates of the American Medical Association is scheduled for a session to be held in Chicago, December 2-6. The House of Delegates will no doubt at that time state officially the point of view of the American Medical Association on the President's proposals.

THE PELLAGRA PROBLEM

The discovery that a deficiency of niacin is directly related to the development of pellagra in man and blacktongue in dogs has not completely clarified the etiology of these conditions. For example, the relatively high incidence of pellagra in maize-eating populations is not entirely thus explained, since corn contains approximately the same amount of niacin as many other foods, such as eggs, milk and oats.¹ Also the early observations of Goldberger and his associates that various protein foods and, indeed, the amino acids tryptophan and cystine exert some beneficial effect in human pellagra indicates that factors in addition to niacin may be involved.

The results of recent experimental studies on the pellagra problem appear to be valuable in elucidating these two puzzling questions. Blacktongue, the canine counterpart of pellagra in man, cannot be produced in dogs by a niacin low synthetic diet adequate in all other respects unless corn grits is added.² The effect of corn grits can be nullified by the addition of niacin.³ Even the rat, a species notoriously resistant to lack of niacin, will show inhibition of growth when corn grits is added to the ration.⁴ The effect is nullified by niacin, as in the dogs, or by increasing the protein intake. The most recent contribution to the problem⁵ demonstrates that the addition of the amino acid tryptophan alone

will likewise counteract the effect of corn grits, thus confirming experimentally an observation made long ago in pellagrins by Goldberger.⁶

A published explanation of the apparent synergistic relationship between tryptophan (and protein) and niacin, on the one hand, and the antagonistic effect of corn, on the other, is not yet forthcoming. However, the suggestion⁶ that the synthesis of niacin by the intestinal flora may be involved appears logical. According to this view the addition of corn grits may decrease the number of niacin synthesizing micro-organisms in the intestinal flora and thus lessen the amount of niacin available to supplement an inadequate niacin intake. The addition of tryptophan or protein, on the other hand, may favor an increase of the niacin synthesizing organisms and thus nullify the effect of corn. The fact that the proteins of corn are comparatively low in tryptophan may also be a related factor. Further studies on this important problem will be awaited with interest.

RECONVERSION OF THE 9-9-9 HOUSE OFFICER PROGRAM

The Procurement and Assignment Service has now announced its program for reconversion of the 9-9-9 program (see page 878, this issue). The Army and Navy have agreed to the plan. The present interns, most of whom will complete nine months of internship about April 1, 1946, will be permitted to continue the internship until July 1, 1946. Should hospitals be unable to accommodate these men plus the new interns who will commence their appointments about April 1, those who hold commissions and have completed their nine months of intern training will be ordered to active duty. New interns appointed April 1, 1946 will be allowed to continue until July 1, 1947, by which time most medical schools hope to be graduating classes annually every June.

Commissioned officers who are serving as junior or assistant residents will be called on completion of their eighteen months of hospital work about April 1, 1946 and (senior) residents completing twenty-seven months will also be called at that time. Exceptions will be made in the deferment of commissioned officers to a second or third nine months hospital appointment only rarely, in "cases in which their services are absolutely essential" and "the Procurement and Assignment Service and the Surgeons General are convinced that every effort to obtain the services of veterans, physically disqualified or otherwise ineligible men or of women has been made."

The primary purposes of this plan are (a) to begin moving toward a peacetime status of twelve months internships commencing each July, while still providing replacements for the Army and Navy and (b) to pro-

vide more residency positions for returning physician veterans who are and will be seeking such training in large numbers. Hospitals are urged to "begin at once to appoint veterans to every staff position so that, with rare exception, every military resident can be called to active duty not later than April 1, 1946." As soon as a veteran is adequately trained to replace a commissioned officer resident, that resident will be called to active duty even before April 1, 1946. Hospitals are again reminded that veterans do not count on their house officer quotas. These regulations should be studied with care by all concerned.

The Army apparently proposes to continue the A. S. T. P. in medical schools if Congress allocates funds and to require medical schools to continue the accelerated program even though relatively few A. S. T. P. students will remain in school. Should the Army persist in this unreasonable program, the plans of several medical schools to provide special work for physician veterans next spring or summer cannot be consummated. Furthermore, medical school calendars will be disoriented with the house officer program outlined by the Procurement and Assignment Service and inordinate confusion will result. The Army cannot justify a continuation of acceleration in medical schools desiring to decelerate, and the schools should refuse to accede to the demand.

The foregoing represents the new policy of the Procurement and Assignment Service and the Surgeons General of the Army and Navy. Unfortunately, other existing Army regulations are in conflict with the commendable purpose and successful operation of this plan.

RESTLESS LEGS

Axel Ekblom¹ reports a "hitherto virtually unknown disease which, because of its prevalence and the torment it causes in severe cases, is of great practical importance." The symptoms seem to be purely subjective and consist of peculiar paresthesias, a feeling of weakness in the legs and a sensation of cold in the feet. The paresthesias are the most characteristic signs of the disease and are therefore important for the diagnosis. They are experienced over the inner aspect of the legs, sometimes in the thighs but rarely in the feet. The arms may be involved. The patients have difficulty in clearly defining this sensation and refer to it most frequently as "crawling." Characteristically, the sensation develops only when the legs are still, most often after the patient retires for the night. For relief the patients move their legs continually or get up and walk about. Their sleep may be disturbed night after night for years with periods of improvement and exacerbation. In its most severe form the disease cause-

6. Goldberger, Joseph, and Tanner, W. F.: *Pub. Health Rep.* 37: 2 (March 5) 1922; 39: 37 (Jan. 23) 1924; 40: 53 (Jan. 9) 1925.

1. Ekblom, K. A.: *Restless Legs*, *Acta med. Scandinav.*, supplement 158, 1945.

great suffering. The disease or syndrome occurs in two main forms: one characterized entirely or mainly by paresthesia and termed by the author "asthenia crurum paraesthetica" and the other, in which pain predominates and which the author calls "asthenia crurum dolorosa." The author uses the term "restless legs" for both groups. The author encountered the condition 18 times among 4,259 persons, 2,411 men and 1,848 women, who visited the neurologic outpatient service of the Serafimer Hospital, Stockholm, during the year 1944. Altogether the author observed, between 1943 and 1945, 34 moderately severe and severe cases of asthenia crurum paraesthetica, 15 cases of the asthenia crurum dolorosa and 65 cases in which the symptoms were so mild that they did not require any treatment.

The paresthetic variety is an easily recognizable condition, probably closely related to acroparesthesia and nocturnal burning feet. The painful variety consists of mild to moderate aching localized in the same situations as the paresthesia. The condition is often worse when the patient is resting and forces him to move his legs. Generally speaking, continuous paresthesia points to an organic lesion of the nervous system, while intermittent paresthesia of the type described in this syndrome points to a functional disorder possibly of vasomotor nature. The author's experience with two vasodilating drugs (Doryl, Merck, carbaminoylcholine chloride and Priscol, Ciba, benzylinimidazolin hydrochloride) lend further support to the vasomotor theory of the condition. However, the author admits that the part which the treatment played in the improvement in the long run is difficult to determine.

A description of a similar syndrome was given by Wittmaack in 1861. This author referred to a condition described by older physicians as "anxietas tibiærum." The only other reference is to be found in an article published by Allison² in 1943 in which he speaks of "leg jitters" as a common minor ailment which he had never seen described. According to Allison the patients experience "a curious, unlocalized, restlessness in one or both legs. It is not quite a pain but is distinctly unpleasant. Massage has no effect, but getting up and walking about may give relief. The disagreeable sensation stops at once on chewing $\frac{1}{100}$ grain of nitroglycerin, suggesting that the cause is vascular."

Ekbom believes that the reason why this syndrome of anxietas tibiærum has been forgotten is that the interest of the neurologists more recently has been centered on neuroses, the psychologic background receiving main attention. Little interest was paid to the clinical features of paresthesias during the twentieth century. The tendency is to label conditions with unusual symptoms as "hysteria," "psychoneurosis," "psychic pain" and the like.

Current Comment

APTITUDE TESTS FOR VOCATIONAL GUIDANCE

Tests for the appraisal of aptitudes and interests of high school students, with special reference to education and choice of a vocation, have achieved wide recognition. Certainly much useful information can be derived from the competent use of psychologic tests and of interest schedules. Tests of this kind have been used extensively by the military forces. There is good scientific evidence favoring the use of tests, but they must be given by people who know their interpretation and limitations. Unfortunately there are many promoters who advertise counseling services together with tests who do not themselves have technical competence in their use. These are probably the very men who come to the attention of the public more than those who are really qualified to give and interpret the tests properly. In differentiating between those who are competent it is useful to ask the qualifications of the senior man or owner of a firm that advertises such services. If he is himself a member of the American Psychological Association and if his examiners are also so qualified, one can assume that the services are reasonably satisfactory. A useful procedure is to make inquiry with the department of psychology in the nearest college. Such inquiry will usually bring information about the capable people in the locality. The value of vocational guidance is unquestionable but is definitely limited by the training of those performing the tests. Furthermore, aptitude testing cannot be considered infallible and must be viewed as subject to modification as the result of continued experience.

CHEMOTOXIC MENTAL DISEASE

Interest in mental diseases has increased because of new problems associated with the war. Mental patients occupy a larger number of beds in institutions than any other group of special patients, and for a longer period. Mental disease may be directly or indirectly related to infection (syphilis, encephalitis, malaria), endocrine disorders (pregnancy, thyrotoxicosis), cerebral arteriosclerosis and to various toxic chemicals. Undoubtedly the importance of chemotoxic factors is increasing on account of industrial developments, medicinal trends and habits associated with the war effort. The proper recognition of causal relations between neurotoxic chemicals and mental disorders becomes, therefore, more and more important for their control. Mental diseases may follow the chronic use of morphine, cocaine, marihuana, bromides, alcohol and occasionally barbiturates. Poisoning with nitrous oxide, potassium thiocyanide,¹ atabrine and sulfonamides² may also lead to

serious and sometimes prolonged psychotic episodes. Generally less appreciated is the psychotic action of several chemicals extensively produced and used in industry and in part sold to the public as constituents of finished products. Carbon monoxide,³ carbon disulfide,⁴ manganese, nicotine, lead and lead compounds, especially the volatile aliphatic compounds, mercurials, particularly the volatile alkyl derivatives,⁵ and organic nitrites are examples. These chemicals have caused many accidental or occupational poisonings associated with transitory or permanent mental disorders. The action of some of these substances on the nervous system is insidious. Thus diethyl mercury and dimethyl mercury salts, which are used as fungicidal dressings for seed grain, may produce nervous symptoms only some weeks or months after exposure without causing at the same time manifestations of typical mercury poisoning. A similar specific neurotropic action is displayed by tetraethyl lead, which produces cerebral symptoms because of its fat soluble properties. Close or prolonged contact with these agents may lead to permanent and progressive psychotic conditions.

THE TIME THAT PHYSICIANS SPEND WITH PATIENTS

Several efforts have been made to estimate the number of physicians necessary to supply satisfactorily medical care to a community by determining the amount of time required to care for patients. A recent report¹ states the time spent on their patients by six physicians engaged in private practice in a war industry area in 1944. The six physicians held office hours on a rotating schedule in two war housing projects. They held 318 office periods, comprising 1,602 patient visits, during the first three months of 1944. The average amount of time spent per patient by the six physicians varied widely—from 12.2 to 21.3 minutes; as more patients were seen during a specific office period the amount of time per patient decreased, thus representing a speed-up in the work of the physician. This suggested to the investigator that the physician is generally "aware of the number of patients waiting to see him and tended to adjust the speed of his work accordingly." The average time spent by six physicians in two war housing projects in seeing their patients cannot possibly give a true index of the adequacy of the medical care or the number of physicians which are necessary to care for the needs of any other population group. Patients differ enormously in the amount of care needed, not only between patient and patient, but between the same patient on different occasions. Different physicians also do not work with the same speed or efficiency. Indeed, there are so many factors involved—

nature of disease, talkativeness of patient or doctor, procedures attempted in single visit, nature of the communities, conditions of practice and the like—that these averages are quite meaningless. The only criterion which can satisfactorily meet the ideals of the medical profession involves the expenditure of as much time by the physician for each patient as is necessary to make a correct diagnosis and to institute the best available therapy on that patient. Even though this ideal is not always attained, even in the practices of physicians in housing projects, physicians generally cannot accept any yardstick that might interfere with this objective.

SHORTAGE OF PENICILLIN

Apparently a definite shortage of penicillin for injection prevails in many places, and physicians are asking the reason for this shortage. A number of factors have produced the present short supply. Included are strikes, difficulty in maintaining production because of contamination during fermentation, increased export, the use of poor quality corn steep liquor and the manufacture of penicillin mixtures. Steps are being taken to overcome the penicillin shortage. Export controls have been suggested to permit records of the quantity of penicillin leaving the United States. Directives giving hospitals first call on penicillin production have also been proposed. A higher grade of corn steep liquor is being sought. Another step which should be undertaken by the manufacturers until the present shortage is alleviated is the discontinuance of doubtfully acting mixtures. Penicillin for injection purposes is truly a life-saving measure and its distribution should be given priority over the manufacture and distribution of over-the-counter items of less value. Judging from letters and telegrams that have come to the headquarters of the American Medical Association, resentment is developing among physicians unable to secure this product for serious cases of disease.

YEAST AS FOOD

Attention has been called¹ to the manifold ways in which micro-organisms have been useful to man. Such processes as the curing of cheese, leavening of breads and fermentation of wines employ the peculiar metabolic activity of the yeast, mold or bacteria concerned; during the recent war the practicability of using the micro-organism itself as a food has been demonstrated, notably with yeast. Postwar needs for nutriment have led the British government to stimulate the production of yeast in Jamaica and in other islands of its British West Indies where sugar cane can be grown.² The yeast isolated from sugar cane is not only a rich source of protein of high biologic value but also contains all of the B vitamins and, if present plans mature, should provide these dietary essentials at relatively low cost. By thus utilizing the natural resources of these islands, progress may be made in combating the poverty so long associated with this region.

MEDICINE AND THE WAR

PROCUREMENT AND ASSIGNMENT SERVICE FOR PHYSICIANS, DENTISTS AND VETERINARIANS

RECONVERSION OF THE 9-9-9 PROGRAM

The 9-9-9 program was devised in order to supply American hospitals with residents. Without it every commissioned officer, which represented 80 per cent of each class, would have been called to active duty at the end of twelve months of internship and the American hospitals would have been practically devoid of residents. The Procurement and Assignment Service made arrangements with the Surgeons General so that a sufficient number of officers could have their active duty orders delayed and the hospitals could have a minimum supply of residents with which to operate during the war. The whole plan constituted a loan of military personnel to civilian institutions by the Surgeons General, and they were willing to enter into the plan because it was perfectly obvious that there was no other supply available with which to keep these hospitals operating.

Increasing numbers of veterans who have seen active duty are becoming available for filling such positions, and therefore the Surgeons General are convinced that it is in order to call to active duty as rapidly as possible every commissioned officer who has not been on active duty. Hospitals, therefore, must begin at once to appoint veterans to every staff position so that, with rare exception, every military resident can be called to active duty not later than April 1, 1946. As soon as a veteran has been adequately trained to replace a commissioned officer resident, that officer should be called to active duty at once without regard to whether or not he has completed the full term of his present deferment. The hospital must notify the state chairman for physicians of the Procurement and Assignment Service of the availability of such officers at once. State chairmen must watch these developments closely. At present veterans will not count in hospital quotas and it will be of great advantage to the hospitals to accept veterans as replacements for the officers who do count in quotas. The great advantage to hospitals in accepting veterans promptly is that they will be orientated to their position before April 1 in anticipation of the fact that after July 1 such veterans will be practically the sole source of supply of residents for civilian hospitals.

Hospitals and commissioned officers now serving as residents are reminded that any contract with hospitals is wholly subsidiary to their legal obligation to the Army and Navy and that each individual is subject to active duty orders at the discretion of the Surgeons General.

Present deferments were granted by the Surgeons General prior to VE day when there was no other supply available to the hospitals. In many institutions veterans are applying by the scores for hospital appointments, and hospitals should accept them to the greatest extent possible in anticipation of the fact that those not having been on active duty will be called.

In those cases in which the hospital desires the services of an officer on active duty in the Army to fill a residency and the hospital is willing to release a deferred commissioned resident who has not been on active duty before the termination of his present deferment period in exchange and he is an officer (1) who has been on active duty for two years or more, (2) who is now stationed within the continental United States and (3) who would accept the appointment, a request for the release of that officer under War Department Circular 296 through the Procurement and Assignment Service will receive immediately prompt and favorable consideration by the Surgeon General of the Army. This replacement possibility does not extend to officers on duty with the Navy.

The Procurement and Assignment Service will continue to recognize its responsibility toward the hospitals, and in those individual instances, very limited in number, in which hospitals are unable to secure a veteran after exhausting every effort or an officer who qualified under the War Department Circular 296 will be given consideration by the Procurement and Assignment

Service and the Offices of the Surgeons General. Subject to the foregoing general provisions the reconversion from the 9-9-9 program to a peacetime twelve month service will be conducted in accordance with the following plan: (This outline applies to the April group. Information concerning those who finish their present term before April and after April will be released in the near future.)

SECTION I

A. Each commissioned officer who is an intern terminating his nine months of internship on April 1, 1946 will continue in his present internship until July 1, 1946. (For exceptions see section II.)

B. Each commissioned officer who is a junior resident terminating his junior residency on April 1 (if he has not already been replaced by a veteran prior to April 1) will be called to active duty on April 1 except in rare cases in which special request for his service is submitted to and approved by the Procurement and Assignment Service and the Surgeon General, such request to be effective only until he is replaced by a veteran and not beyond July 1, 1946.

C. Each commissioned officer who is senior resident and who is completing his twenty-seven months of service in a hospital following graduation will be called to active duty on or about April 1, 1946 if not replaced prior to that date by a veteran.

D. Senior students who graduate on or about April 1, 1946 are to be accepted for internship on that date. This new group of interns will be allowed to serve internships until July 1, 1947. This means that hospitals would have a maximum of twice their quota of interns from April to July and their quota of interns from July to the following July. In view of this and in order to maintain equitable distribution of the intern supply, *quotas* for interns will be maintained at their present levels.

SECTION II

A. The present interns (referred to in paragraph A, section I) will be called to active duty on July 1, 1946 except (1) those who are called to duty between April 1 and July 1 because the hospitals cannot facilitate both the old and new groups of interns for three full months of overlapping service; and (2) those rare cases in which their services are absolutely essential for an additional period in civilian hospitals. Their services will be deemed necessary only in those cases in which the Procurement and Assignment Service and the Surgeons General are convinced that every effort to obtain the services of veterans, physically disqualified or otherwise ineligible men or of women has been made. [N. B.: If Congress votes funds to continue the ASTP beyond June 30, 1946 the military group in the following class (unless the Army Training Service abandons its present acceleration demands) will become available for internship on Jan. 1, 1947. This would produce a six month overlap from January to July, but it is hoped that this can be avoided.]

B. The present junior residents (referred to in paragraph D, section I) will be called to active duty as soon as replaced by a veteran with the same exceptions stated in paragraph A, section I.

C. (Blank).

D. The new graduates (referred to in paragraph D, section I), who will complete twelve months of internship on or before July 1, 1947 will be called to active duty on that date. These men may have as much as fifteen months of internship, that is, April 1, 1946 to July 1, 1947.

SECTION III

By April 1, 1946 hospitals will be almost entirely dependent on nonmilitary personnel to fill residencies.

This program does not contemplate an interference with the present policy of not including veterans in quotas. In fact, it emphasizes the importance of acquiring the services of such veterans at the earliest possible moment so that they will be adequately trained to serve as replacements for officers now deferred to April 1 and for the period when they will represent practically the entire supply—after July 1, 1946.

In the interest of adequate distribution of the available supply of veterans, it is expected that hospitals will not fill their house staff out of proportion to present quotas. These veterans should be used first as replacements, and present quotas for residents should not be exceeded until all deferred commissioned officers who have not been on active duty have been released from that particular hospital. This is not contrary to the policy of not counting veterans in quotas until they are sufficiently trained to be used as replacements.

ARMY

GENERAL KIRK RECEIVES DISTINGUISHED SERVICE MEDAL

Major Gen. Norman T. Kirk, Surgeon General of the Army, was recently awarded the Distinguished Service Medal by Gen. Brehon Somervell, commanding general of the Army Service Forces, in recognition of his "outstanding leadership . . . in directing the largest Medical Department in the history of the United States Army." According to the official citation, "By careful planning, efficient administration and dynamic example he [General Kirk] made possible extraordinary care for sick and wounded American soldiers—care which has never been equaled in any war. He supervised the selection of qualified medical specialists who were assigned to posts stretching from the forward areas to general hospitals in the zone of the interior and combined their exceptional talents with a prompt evacuation system to achieve unprecedented results. Under his able guidance every effort was made to utilize the newer methods of medical and surgical treatment and to develop new techniques. His plans for the care of battle casualties and outstanding efforts to prevent disease among the troops resulted in an enormous reduction in mortality and morbidity. Bearing tremendous responsibilities, General Kirk accomplished his trying task in a distinctly superior manner, thereby making a major contribution to the success of American arms." General Kirk graduated from the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, in 1910 and entered the service in 1912.

PLASTIC EYE CENTERS

In keeping with the Army's program to establish sufficient plastic eye centers to supply the needs of patients requiring prostheses, Fitzsimons and O'Reilly general hospitals, Denver and Springfield, Mo., respectively, have been added to the list of general hospital centers. Other army general hospitals now producing plastic eyes are Thayer, Birmingham, McGuire, Hammond, Barnes, Dibble, Newton D. Baker, Tilton (also Waltham Regional Hospital), Rhoads, Halloran, McCloskey, Wakeman, Glennan, Cushing, Ashburn, Crile, Northington, Gardiner, Lawson, Walter Reed, Percy Jones, Brooke, William Beaumont, Finney, Harmon and Valley Forge.

AWARD OF MERITORIOUS SERVICE UNIT PLAQUE

A Meritorious Service Unit Plaque was recently awarded to the 318th Medical Battalion for superior performance and outstanding devotion to duty from Nov. 15, 1944 to Sept. 20, 1945. This unit was charged with the important and difficult task of providing medical care, treatment and evacuation facilities for the entire personnel of the 93d Infantry Division, although they were distributed on various bases over a vast area of the Pacific. As the result of devotion to duty, long hours and cheerful cooperation on the part of all personnel, excellent medical care and treatment was provided in spite of the battalion being under

It will not be necessary to submit forms 218 for the continuation of interns for the period from April 1 to July 1, referred to in paragraphs A and B, section I. It will be presumed, however, that the junior residents referred to in paragraph B, section I, practically without exception, will not be requested for this period and will be released prior to but not later than April 1 and as soon as they can be satisfactorily replaced by officers discharged or separated from the service.

The necessity of reconverting from the 9-9-9 program as rapidly as possible cannot be emphasized too strongly and to the greatest extent possible for the purpose of returning to the July to July twelve month internship this coming year. The most available and safest supply of physicians to serve residencies will be these who have completed their military obligation to the nation during the war and the duration of the emergency.

strength in personnel, both commissioned and enlisted. Despite the difficult and trying situations the unit maintained high standards of administration and continued improvements in medical service, housekeeping, sanitation, military courtesy and discipline. The appearance of personnel was at all times exemplary. The unit average on ordnance inspections was among the highest in the 93d Infantry Division, notwithstanding the fact that class 2 and 3 vehicles comprised 90 per cent of the vehicles. The unit was at all times preeminent in its achievements and received commendations from various visiting officials, including the Surgeon General of the Army. Throughout the entire period of operation a high degree of morale and *esprit de corps* was maintained.

ARMY AWARDS AND COMMENDATIONS

Colonel Perrin A. Long

Col. Perrin A. Long, Baltimore, was recently awarded the Legion of Merit in recognition of his work as medical consultant to the surgeon, Mediterranean Theater of Operations, from Jan. 3, 1943 to Aug. 1, 1945. The official citation stated in part that, "as medical consultant to the surgeon, North African and later the Mediterranean Theater of Operations, Colonel Long efficiently organized the medical service of hospitals and other medical units and by his teaching and counsel developed such successful therapeutic methods of handling malaria, bacillary dysentery and other infectious diseases that mortality and permanent disability among American troops were reduced to an unprecedented low level." Dr. Long graduated from the University of Michigan Medical School, Ann Arbor, in 1924 and entered the service Aug. 27, 1942.

Colonel Arthur B. Welsh

The Legion of Merit was recently awarded to Col. Arthur B. Welsh, Washington, D. C. The citation stated that "he rendered conspicuous and meritorious service in the medical program at the Army from November 1941 to May 1945 in his capacity as deputy director, then as director of the Plans Division and later as deputy chief of the Operations Service, Surgeon General's Office. He envisioned, and established as his objective an all inclusive and comprehensive policy for the early treatment, hospitalization and evacuation of our sick and wounded soldiers. He formulated the Medical Department Mobilization Plan, which resulted in a well balanced medical service, as evidenced by the extremely low mortality rates during the all out prosecution of the war. He also formulated and effected the plan to increase the bed capacity of general hospitals employed overseas, resulting in an economy in the use of personnel and equipment at a time when the shortage of both was critical and the requirements greatest. His keen judgment and breadth of vision were apparent in the effectiveness of the operations of the Medical Service overseas." Dr. Welsh graduated from the University of Pittsburgh School of Medicine in 1925 and entered the service June 10, 1925.

Colonel Frank E. Stinchfield

The Legion of Merit was recently awarded to Col. Frank E. Stinchfield, formerly of New York, for "exceptionally meritorious conduct in the performance of outstanding service as commanding officer, — Station Hospital, during the period August 1943 to August 1944. Under adverse conditions Lieutenant Colonel Stinchfield developed this 4,000 bed capacity. In the short time he has operated this hospital it has rehabilitated and returned to duty approximately 85 per cent of its patients. Through his diligence, vision and ingenuity he developed a rehabilitation program so wide in scope that thousands of men

were sent back to duty completely rehabilitated. The resultant conservation of manpower has materially aided the progress of the war. Lieutenant Colonel Stinchfield established two schools to make his extensive program of rehabilitation familiar to as many as possible. Faced with lack of proper equipment and a shortage of qualified personnel, he improvised his equipment and trained his own personnel. Since the inception of the program Lieutenant Colonel Stinchfield's staff has trained hundreds of officers in the principles and methods of rehabilitation." Dr. Stinchfield graduated from Northwestern University Medical School, Chicago, in 1935 and entered the service Feb. 15, 1942.

MISCELLANEOUS**WARTIME GRADUATE MEDICAL MEETINGS**

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

Torney General Hospital, Palm Springs: The Rh Factor, Capt. George Macer, December 4; Hemolytic Streptococcus Respiratory Infections and Their Sequelae, Dr. Robert E. Solley, December 18.

A. A. F. Regional and Convalescent Hospital, Santa Ana Army Air Base: Contagious Diseases, Comdr. R. A. Trombley, December 4; Compound Fractures, Comdr. P. E. McMasters, December 18.

Camp Cooke Station Hospital, Lompoc: The Cancer Problem in Service Personnel, Lieut. J. S. Binkley, December 5; Problems in Tuberculosis, Comdr. W. L. Rogers and Comdr. A. W. Hobby, December 19.

Hoff General Hospital, Santa Barbara: The Cancer Problem in Service Personnel, Lieut. J. S. Binkley, December 5; Problems in Tuberculosis, Comdr. W. L. Rogers and Comdr. A. W. Hobby, December 19.

U. S. Naval Hospital, San Diego: The Classification and Diagnosis of the Anemias, Dr. A. G. Foord, December 6.

U. S. Naval Air Training Station, San Diego: Burns, Capt. H. T. D. Kirkbaum, December 7; The Penicillin Treatment of Syphilis and Gonorrhea, Comdr. W. W. Duenling, December 21.

U. S. Regional Hospital, Pasadena: The Rh Factor, Capt. George Macer, December 10.

Station Hospital, Fort Ord: Diseases of the Lungs and Their Treatment, Dr. Philip H. Pierson, December 15.

U. S. Naval Hospital, Treasure Island: Diagnosis of Atypical Anemias, Dr. Stacy R. Mettler, December 7.

Station Hospital, Camp Roberts: Diseases of the Thyroid: Clinical Considerations, Dr. Mayo H. Soley, December 8.

Station Hospital, Chico Army Air Base, Chico: Laboratory Aids in the Diagnosis of Disease, Dr. Jesse L. Carr, December 6.

Station Hospital, Stockton Air Field, Stockton: The Fundamentals of Endocrine Diagnosis, Dr. Roberto F. Escamilla, December 12.

U. S. Naval Hospital, Santa Margarita Ranch: Communicable Diseases, Major Norman Nixon, December 13; Problems Associated with the Surgery of the Biliary Tract, Capt. Howard K. Gray, December 27.

Dibble General Hospital, Menlo Park: The Surgical Anatomy of Hernia, Dr. Harold H. Lindner, December 3.

Illinois

Gardiner General Hospital, Chicago: Surgical Management of Tuberculosis, Dr. Jerome Head, November 28.

Pennsylvania

U. S. Naval Hospital, Philadelphia: Emotional Factors in Physical Illness, Dr. Earl D. Bond, December 7; Difficulties in the Diagnosis of Surgical Lesions of the Upper Urinary Tract, Dr. Leon Herman, December 28.

Virginia

Regional Hospital, Camp Lee, Petersburg: The Treatment of Vascular Hypertension by Extensive Sympathectomy, Dr. C. C. Coleman, December 14.

UNRRA NEWS**Plastic Surgery Team to Yugoslavia**

According to a recent release from the United Nations Relief and Rehabilitation Administration, Washington, D. C., a plastic surgery team with special training and experience gained in England during the war will be dispatched to Belgrade, Yugoslavia, to train doctors and nurses there in the latest techniques. Dr. Neville M. Goodman, director at London of UNRRA's European division of health, stated that "casualties among both soldiers and civilians in Yugoslavia created a large number of cases needing plastic surgery. The team of experts being sent by UNRRA will train enough Yugoslav surgeons so that they can carry on the necessary work without further assistance."

The team, which includes three surgeons, three specially trained nurses, a dental operator and a medical secretary, will be set up in a Belgrade hospital which escaped war damage and which is to be provided by the Yugoslav government. All the members of the team are drawn from the staff of a widely known British plastic surgery hospital near Basingstock. The team as a whole will remain in Yugoslavia for six months, but members will be relieved at intervals by different surgeons who will demonstrate and give training in the techniques of other schools of plastic surgery.

**CAPTAIN LOWELL T. COGGESHALL
AWARDED GORGAS MEDAL**

The Gorgas Medal, which has been awarded annually since 1942 by Wyeth Inc., Philadelphia, was given this year to Capt. Lowell T. Coggeshall (MC), U.S.N.R., expert on tropical diseases, "for distinguished service to our military forces in establishing new principles in the management of patients suffering from psychic disturbances as well as physical deterioration from the effects of malaria and filariasis. Captain Coggeshall instituted the system of psychosomatic rehabilitation by which thousands who faced discharge attributed to malaria and filariasis were returned to full duty. His was not only a brilliant accomplishment in a special field of military medicine, but he also inaugurated a new epoch in the treatment of a wide variety of diseases."

The medal was presented to Captain Coggeshall by Frank F. Law, vice president of Wyeth Inc., at a dinner in his honor at the Mayflower Hotel, Washington, D. C., October 29 and carries with it an honorarium of \$500. The award was established in memory of Surg. Gen. William Crawford Gorgas, U. S. Army.

**DALLAS COUNTY MEDICAL SOCIETY
LISTS RETURNED MEMBERS**

A campaign is being sponsored by the Dallas County Medical Society and the Dallas Southern Clinical Society whereby its members who have returned from service will be listed in each of the two Sunday papers published in that city. A different group of names is used each month and the campaign is to be continued for a minimum of six months.

In addition, a placard with the following legend is displayed in the reception room of every Dallas physician:

"May We Suggest, WHEN YOUR DOCTOR RETURNS FROM THE SERVICE RETURN TO YOUR DOCTOR"

A NATIONAL HEALTH PROGRAM

Message to Congress on a National Health Program from President Harry S. Truman

To the Congress of the United States:

In my message to the Congress of Sept. 6, 1945 there were enumerated in a proposed economic bill of rights certain rights which ought to be assured to every American citizen.

One of them was "the right to adequate medical care and the opportunity to achieve and enjoy good health." Another was the "right to adequate protection from the economic fears of . . . sickness. . . ."

Millions of our citizens do not now have a full measure of opportunity to achieve and enjoy good health. Millions do not now have protection or security against the economic effects of sickness. The time has arrived for action to help them attain that opportunity and that protection.

The people of the United States received a shock when the medical examinations conducted by the Selective Service System revealed the widespread physical and mental incapacity among the young people of our nation. We had had prior warnings from eminent medical authorities and from investigating committees. The statistics of the last war had shown the same condition. But the Selective Service System has brought it forcibly to our attention recently in terms which all of us can understand.

As of April 1, 1945 nearly 5,000,000 male registrants between the ages of 18 and 37 had been examined and classified as unfit for military service. The number of those rejected for military service was about 30 per cent of all those examined. The percentage of rejection was lower in the younger age groups and higher in the higher age groups, reaching as high as 49 per cent for registrants between the ages of 34 and 37. In addition, after actual induction, about a million and a half men had to be discharged from the Army and Navy for physical or mental disability, exclusive of wounds; and an equal number had to be treated in the armed forces for diseases or defects which existed before induction.

Among the young women who applied for admission to the Women's Army Corps there was similar disability. Over one third of those examined were rejected for physical or mental reasons.

These men and women who were rejected for military service are not necessarily incapable of civilian work. It is plain, however, that they have illnesses and defects that handicap them, reduce their working capacity or shorten their lives.

It is not so important to search the past in order to fix the blame for these conditions. It is more important to resolve now that no American child shall come to adult life with diseases or defects which can be prevented or corrected at an early age.

Medicine has made great strides in this generation, especially during the last four years. We owe much to the skill and devotion of the medical profession. In spite of great scientific progress, however, each year we lose many more persons from preventable and premature deaths than we lost in battle or from war injuries during the entire war.

We are proud of past reductions in our death rates. But these reductions have come principally from public health and other community services. We have been less effective in making available to all of our people the benefits of medical progress in the care and treatment of individuals.

In the past, the benefits of modern medical science have not been enjoyed by our citizens with any degree of equality. Nor are they today. Nor will they be in the future unless government is bold enough to do something about it.

People with low or moderate incomes do not get the same medical attention as those with high incomes. The poor have more sickness, but they get less medical care. People who live in rural areas do not get the same amount or quality of medical attention as those who live in our cities. Our new economic bill of rights should mean health security for all,

regardless of residence, station or race everywhere in the United States. We should resolve now that the health of this nation is a national concern; that financial barriers in the way of attaining health shall be removed; that the health of all its citizens deserves the help of all the nation.

There are five basic problems which we must attack vigorously if we would reach the health objectives of our economic bill of rights:

Distribution

1. The first has to do with the number and distribution of doctors and hospitals. One of the most important requirements for adequate health service is professional personnel—doctors, dentists, public health and hospital administrators, nurses and other experts. The United States has been fortunate with respect to physicians. In proportion to population it has more than any large country in the world, and they are well trained for their calling. It is not enough, however, that we have them in sufficient numbers. They should be located where their services are needed. In this respect we are not so fortunate. The distribution of physicians in the United States has been grossly uneven and unsatisfactory. Some communities have had enough or even too many; others have had too few. Year by year the number in our rural areas has been diminishing. Indeed, in 1940 there were thirty-one counties in the United States, each with more than a thousand inhabitants, in which there was not a single practicing physician. The situation with respect to dentists was even worse.

One important reason for this disparity is that in some communities there are no adequate facilities for the practice of medicine. Another reason, closely allied with the first, is that the earning capacity of the people in some communities makes it difficult if not impossible for doctors who practice there to make a living.

The demobilization of 60,000 doctors and of the tens of thousands of other professional personnel in the armed forces is now proceeding on a large scale. Unfortunately, unless we act rapidly, we may expect to see them concentrate in the places with greater financial resources and avoid other places, making the inequalities even greater than before the war. Demobilized doctors cannot be assigned. They must be attracted. In order to be attracted, they must be able to see ahead of them professional opportunities and economic assurances.

Inequalities in the distribution of medical personnel are matched by inequalities in hospitals and other health facilities. Moreover, there are just too few hospitals, clinics and health centers to take proper care of the people of the United States.

About 1,200 counties, 40 per cent of the total in the country, with some 15,000,000 people, have either no local hospital or none that meets even the minimum standards of national professional associations. The deficiencies are especially severe in rural and semirural areas and in those cities where changes in population have placed great strains on community facilities. I want to emphasize, however, that the basic problem in this field cannot be solved merely by building facilities. They have to be staffed; and the communities have to be able to pay for the services. Otherwise the new facilities will be little used.

Maternal and Child Care

2. The second basic problem is the need for development of public health services and maternal and child care. The Congress can be justifiably proud of its share in making recent accomplishments possible. Public health and maternal and child health programs already have made important contributions to national health. But large needs remain. Great areas of our country are still without these services. This is especially true among our rural areas; but it is true also in far too many urban communities.

Although local public health departments are now maintained by some 18,000 counties and other local units, many of these have only skeleton organizations, and approximately 40,000,000 citizens of the United States still live in communities lacking full time local public health service. At the recent rate of progress in developing such service, it would take more than a hundred years to cover the whole nation.

If we agree that the national health must be improved, our cities, towns and farming communities must be made healthful places in which to live through provision of safe water systems, sewage disposal plants and sanitary facilities. Our streams and rivers must be safeguarded against pollution. In addition to building a sanitary environment for ourselves and for our children, we must provide those services which prevent disease and promote health.

Services for expectant mothers and for infants, care of crippled or otherwise physically handicapped children and inoculation for the prevention of communicable diseases are accepted public health functions. So too are many kinds of personal services such as the diagnosis and treatment of widespread infections like tuberculosis and venereal disease. A large part of the population today lacks many or all of these services.

Our success in the traditional public health sphere is made plain by the conquest over many communicable diseases. Typhoid fever, smallpox and diphtheria—diseases for which there are effective controls—have become comparatively rare. We must make the same gains in reducing our maternal and infant mortality, in controlling tuberculosis, venereal disease, malaria and other major threats to life and health. We are only beginning to realize our potentialities in achieving physical well-being for all our people.

Research and Education

3. The third basic problem concerns medical research and professional education. We have long recognized that we cannot be content with what is already known about health or disease. We must learn and understand more about health and how to prevent and cure disease.

Research—well directed and continuously supported—can do much to develop ways to reduce those diseases of body and mind which now cause most sickness, disability and premature death—diseases of the heart, kidneys and arteries, rheumatism, cancer, diseases of childbirth, infancy and childhood, respiratory diseases and tuberculosis. And research can do much toward teaching us how to keep well and how to prolong healthy human life.

Cancer is among the leading causes of death. It is responsible for over 160,000 recorded deaths a year and should receive special attention. Though we already have the National Cancer Institute of the Public Health Service, we need still more coordinated research on the cause, prevention and cure of this disease. We need more financial support for research and to establish special clinics and hospitals for diagnosis and treatment of the disease, especially in its early stages. We need to train more physicians for the highly specialized services so essential for effective control of cancer.

There is also special need for research on mental diseases and abnormalities. We have done pitifully little about mental illnesses. Accurate statistics are lacking, but there is no doubt that there are at least two million persons in the United States who are mentally ill and that as many as ten million will probably need hospitalization for mental illness for some period in the course of their lifetime. A great many of these persons would be helped by proper care. Mental cases occupy more than one half of the hospital beds at a cost of about 500 million dollars per year, practically all of it coming out of taxpayers' money. Each year there are 125,000 new mental cases admitted to institutions. We need more mental disease hospitals, more outpatient clinics. We need more services for early diagnosis, and especially we need much more research to learn how to prevent mental breakdown. Also we must have many more trained and qualified doctors in this field.

It is clear that we have not done enough in peacetime for medical research and education in view of our enormous resources and our national interest in health progress. The

money invested in research pays enormous dividends. If any one doubts this, let him think of penicillin, plasma, DDT powder and new rehabilitation technics.

Cost of Medical Care

4. The fourth problem has to do with the high cost of individual medical care. The principal reason why people do not receive the care they need is that they cannot afford to pay for it on an individual basis at the time they need it. This is true not only for needy persons. It is also true for a large proportion of normally self-supporting persons.

In the aggregate all health services—from public health agencies, physicians, hospitals, dentists, nurses and laboratories—absorb only about 4 per cent of the national income. We can afford to spend more for health. But 4 per cent is only an average. It is cold comfort in individual cases. Individual families pay their individual costs and not average costs. They may be hit by sickness that calls for many times the average cost—in extreme cases for more than their annual income. When this happens they may come face to face with economic disaster. Many families, fearful of expense, delay calling the doctor long beyond the time when medical care would do the most good. For some persons with very low income or no income at all we now use taxpayers' money in the form of free services, free clinics and public hospitals. Tax-supported, free medical care for needy persons, however, is insufficient in most of our cities and in nearly all of our rural areas. This deficiency cannot be met by private charity or the kindness of individual physicians. Each of us knows doctors who work through endless days and nights, never expecting to be paid for their services because many of their patients are unable to pay. Often the physician spends not only his time and effort but even part of the fees he has collected from patients able to pay, in order to buy medical supplies for those who cannot afford them. I am sure that there are thousands of such physicians throughout our country. They cannot, and should not, be expected to carry so heavy a load.

Compensation

5. The fifth problem has to do with loss of earnings when sickness strikes. Sickness not only brings doctor bills; it also cuts off income. On an average day there are about 7 million persons so disabled by sickness or injury that they cannot go about their usual tasks. Of these, about 3¼ millions are persons who, if they were not disabled, would be working or seeking employment. More than one half of these disabled workers have already been disabled for six months; many of them will continue to be disabled for years, and some for the remainder of their lives. Every year four or five hundred million working days are lost from productive employment because of illness and accident among those working or looking for work—about forty times the number of days lost because of strikes on the average during the ten years before the war. About nine tenths of this enormous loss is due to illness and accident that is not directly connected with employment and is therefore not covered by workmen's compensation laws.

These, then, are the five important problems which must be solved if we hope to attain our objective of adequate medical care, good health and protection from the economic fears of sickness and disability.

To meet these problems, I recommend that the Congress adopt a comprehensive and modern health program for the nation, consisting of five major parts—each of which contributes to all the others.

Construction

First: Construction of hospitals and related facilities. The federal government should provide financial and other assistance for the construction of needed hospitals, health centers and other medical, health and rehabilitation facilities. With the help of federal funds it should be possible to meet deficiencies in hospital and health facilities so that modern services—for both prevention and cure—can be accessible to all the people. Federal financial aid should be available not only to build new facilities where needed but also to enlarge or modernize those we now have.

In carrying out this program there should be a clear division of responsibilities between the states and the federal government. The states, localities and the federal government should share in the financial responsibilities. The federal government should not construct or operate these hospitals. It should, however, lay down minimum national standards for construction and operation and should make sure that federal funds are allocated to those areas and projects where federal aid is needed most. In approving state plans and individual projects, and in fixing the national standards, the federal agency should have the help of a strictly advisory body that includes both public and professional members. Adequate emphasis should be given to facilities that are particularly useful for prevention of diseases—mental as well as physical—and to the coordination of various kinds of facilities. It should be possible to go a long way toward knitting together facilities for prevention with facilities for cure, the large hospitals of medical centers with the smaller institutions of surrounding areas, the facilities for the civilian population with the facilities for veterans. The general policy of federal-state partnership which has done so much to provide the magnificent highways of the United States can be adapted to the construction of hospitals in the communities which need them.

Expansion of Health Services

Second: Expansion of public health, maternal and child health services. Our programs for public health and related services should be enlarged and strengthened. The present federal-state cooperative health programs deal with general public health work, tuberculosis and venereal disease control, maternal and child health services, and services for crippled children. These programs were especially developed in the ten years before the war and have been extended in some areas during the war. They have already made important contributions to national health, but they have not yet reached a large proportion of our rural areas, and in many cities they are only partially developed.

No area in the nation should continue to be without the services of a full time health officer and other essential personnel. No area should be without essential public health services or sanitation facilities. No area should be without community health services such as maternal and child health care. Hospitals, clinics and health centers must be built to meet the needs of the total population and must make adequate provision for the safe birth of every baby, and for the health protection of infants and children.

Present laws relating to general public health, and to maternal and child health, have built a solid foundation of federal cooperation with the states in administering community health services. The emergency maternity and infant care program for the wives and infants of servicemen—a great wartime service authorized by the Congress—has materially increased the experience of every state health agency and has provided much needed care. So too have other wartime programs such as venereal disease control, industrial hygiene, malaria control, tuberculosis control and other services offered in war essential communities. The federal government should cooperate by more generous grants to the states than are provided under present laws for public health services and for maternal and child health care. The program should continue to be partly financed by the states themselves and should be administered by the states. Federal grants should be in proportion to state and local expenditures and should also vary in accordance with the financial ability of the respective states.

The health of American children, like their education, should be recognized as a definite public responsibility. In the conquest of many diseases prevention is even more important than cure. A well rounded national health program should therefore include systematic and widespread health and physical education and examinations, beginning with the youngest children and extending into community organizations. Medical and dental examinations of school children are now inadequate. A preventive health program, to be successful, must discover defects as early as possible. We should therefore see to it that our health programs are pushed most vigorously with the youngest section

of the population. Of course, federal aid for community health services—for general public health and for mothers and children—should complement and not duplicate prepaid medical services for individuals, proposed by the fourth recommendation of this message.

Medical Education and Research

Third: Medical education and research. The federal government should undertake a broad program to strengthen professional education in medical and related fields and to encourage and support medical research. Professional education should be strengthened where necessary through federal grants-in-aid to public and to nonprofit private institutions. Medical research also should be encouraged and supported in the federal agencies and by grants-in-aid to public and nonprofit private agencies.

In my message to the Congress of Sept. 6, 1945 I made various recommendations for a general federal research program. Medical research, dealing with the broad fields of physical and mental illnesses, should be made effective in part through that general program and in part through specific provisions within the scope of a national health program. Federal aid to promote and support research in medicine, public health and allied fields is an essential part of a general research program to be administered by a central federal research agency. Federal aid for medical research and education is also an essential part of any national health program if it is to meet its responsibilities for high grade medical services and for continuing progress. Coordination of the two programs is obviously necessary to assure efficient use of federal funds. Legislation covering medical research in a national health program should provide for such coordination.

Medical Costs

Fourth: Prepayment of medical costs. Every one should have ready access to all necessary medical, hospital and related services. I recommend solving the basic problem by distributing the costs through expansion of our existing compulsory social insurance system. This is not socialized medicine. Every one who carries fire insurance knows how the law of averages is made to work so as to spread the risk and to benefit the insured who actually suffers the loss. If, instead of the costs of sickness being paid only by those who get sick, all the people—sick and well—were required to pay premiums into an insurance fund, the pool of funds thus created would enable all who do fall sick to be adequately served without overburdening any one. That is the principle on which all forms of insurance are based.

During the past fifteen years, hospital insurance plans have taught many Americans this magic of averages. Voluntary health insurance plans have been expanding during recent years; but their rate of growth does not justify the belief that they will meet more than a fraction of our people's needs. Only about 3 per cent or 4 per cent of our population now have insurance providing comprehensive medical care. A system of required prepayment would not only spread the costs of medical care, it would also prevent much serious disease. Since medical bills would be paid by the insurance fund, doctors would more often be consulted when the first signs of disease occur instead of when the disease has become serious. Modern hospital, specialist and laboratory services, as needed, would also become available to all and would improve the quality and adequacy of care. Prepayment of medical care would go a long way toward furnishing insurance against disease itself as well as against medical bills. Such a system of prepayment should cover medical, hospital, nursing and laboratory services. It should also cover dental care as fully and for as many of the population as the available professional personnel and the financial resources of the system permit.

The ability of our people to pay for adequate medical care will be increased if, while they are well, they pay regularly into a common health fund instead of paying sporadically and unevenly when they are sick. This health fund should be built up nationally in order to establish the broadest and most stable basis for spreading the costs of illness and to assure adequate financial support for doctors and hospitals everywhere. If we were to rely on state by state action only, many years would elapse before we had any general coverage. Meanwhile health

service would continue to be grossly uneven, and disease would continue to cross state boundary lines.

Medical services are personal. Therefore the nationwide system must be highly decentralized in administration. The local administrative unit must be the keystone of the system so as to provide for local services and adaptation to local needs and conditions. Locally as well as nationally, policy and administration should be guided by advisory committees in which the public and the medical professions are represented.

Subject to national standards, methods and rates of paying doctors and hospitals should be adjusted locally. All such rates for doctors should be adequate and should be appropriately adjusted upward for those who are qualified specialists. People should remain free to choose their own physicians and hospitals. The removal of financial barriers between patient and doctor would enlarge the present freedom of choice. The legal requirement on the population to contribute involves no compulsion over the doctor's freedom to decide what services his patient needs. People will remain free to obtain and pay for medical service outside the health insurance system if they desire, even though they are members of the system, just as they are free to send their children to private instead of to public schools, although they must pay taxes for public schools. Likewise physicians should remain free to accept or reject patients. They must be allowed to decide for themselves whether they wish to participate in the health insurance system full time, part time or not at all. A physician may have some patients who are in the system and some who are not. Physicians must be permitted to be represented through organizations of their own choosing and to decide whether to carry on in individual practice or to join with other doctors in group practice in hospitals or in clinics.

Our voluntary hospitals and our city, county and state general hospitals, in the same way, must be free to participate in the system to whatever extent they wish. In any case they must continue to retain their administrative independence.

Voluntary Organizations

Voluntary organizations which provide health services that meet reasonable standards of quality should be entitled to furnish services under the insurance system and to be reimbursed for them. Voluntary cooperative organizations concerned with paying doctors, hospitals or others for health services, but not providing services directly, should be entitled to participate if they can contribute to the efficiency and economy of the system.

None of this is really new. The American people are the most insurance minded people in the world. They will not be frightened off from health insurance because some people have misnamed it "socialized medicine."

I repeat—what I am recommending is not socialized medicine. Socialized medicine means that all doctors work as employees of government. The American people want no such system. No such system is here proposed. Under the plan I suggest, our people would continue to get medical and hospital services just as they do now—on the basis of their own voluntary decisions and choices. Our doctors and hospitals would continue to deal with disease with the same professional freedom as now. There would, however, be this all important difference: Whether or not patients get the services they need would not depend on how much they can afford to pay at the time.

I am in favor of the broadest possible coverage for this insurance system. I believe that all persons who work for a living and their dependents should be covered under such an insurance plan. This would include wage and salary earners, those in business for themselves, professional persons, farmers, agricultural labor, domestic employees, government employees and employees of nonprofit institutions and their families. In addition, needy persons and other groups should be covered through appropriate premiums paid for them by public agencies. Increased federal funds should also be made available by the Congress under the public assistance programs to reimburse the states for part of such premiums, as well as for direct expenditures made by the states in paying for medical services provided by doctors, hospitals and other agencies to needy persons.

Premiums for present social insurance benefits are calculated on the first \$3,000 of earnings in a year. It might be well to have all such premiums, including those for health, calculated on a somewhat higher amount, such as \$3,600. A broad program of prepayment for medical care would need total amounts approximately equal to 4 per cent of such earnings. The people of the United States have been spending, on the average, nearly this percentage of their incomes for sickness care. How much of the total fund should come from the insurance premiums and how much from general revenues is a matter for the Congress to decide. The plan which I have suggested would be sufficient to pay most doctors more than the best they have received in peacetime years. The payments of the doctors' bills would be guaranteed, and the doctors would be spared the annoyance and uncertainty of collecting fees from individual patients. The same assurance would apply to hospitals, dentists and nurses for the services they render. Federal aid in the construction of hospitals will be futile unless there is current purchasing power so that people can use these hospitals. Doctors cannot be drawn to sections which need them without some assurance that they can make a living. Only a nationwide spreading of sickness costs can supply such sections with sure and sufficient purchasing power to maintain enough physicians and hospitals. We are a rich nation and can afford many things. But ill health which can be prevented or cured is one thing we cannot afford.

Comprehensive Health Program

Fifth: Protection against loss of wages from sickness and disability. What I have discussed heretofore has been a program for improving and spreading the health services and facilities of the nation and providing an efficient and less burdensome system of paying for them. But no matter what we do, sickness will of course come to many. Sickness brings with it loss of wages. Therefore, as a fifth element of a comprehensive health program, the workers of the nation and their families should be protected against loss of earnings because of illness. A comprehensive health program must include the payment of benefits to replace at least part of the earnings that are lost during the period of sickness and long term disability. This protection can be readily and conveniently provided through expansion of our present social insurance system, with appropriate adjustment of premiums.

Insurance against loss of wages from sickness and disability deals with cash benefits rather than with services. It has to be coordinated with the other cash benefits under existing social insurance systems. Such coordination should be effected when other social security measures are reexamined. I shall bring this subject again to the attention of the Congress in a separate message on social security.

I strongly urge that the Congress give careful consideration to this program of health legislation now.

Many millions of our veterans, accustomed in the armed forces to the best of medical and hospital care, will no longer be eligible for such care as a matter of right except for their service connected disabilities. They deserve continued adequate and comprehensive health service. And their dependents deserve it too.

By preventing illness, by assuring access to needed community and personal health services, by promoting medical research and by protecting our people against the loss caused by sickness we shall strengthen our national health, our national defense and our economic productivity. We shall increase the professional and economic opportunities of our physicians, dentists and nurses. We shall increase the effectiveness of our hospitals and public health agencies. We shall bring new security to our people.

We need to do this especially at this time because of the return to civilian life of many doctors, dentists and nurses, particularly young men and women.

Appreciation of modern achievements in medicine and public health has created widespread demand that they be fully applied and universally available. By meeting that demand we shall strengthen the nation to meet future economic and social problems; and we shall make a most important contribution toward freedom from want in our land.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Nov. 19, 1945.

Army Doctors May Be Released on 70 Points by December 15

The present score for the release of doctors by the Army is 80 points, but this may be reduced to 70 points by December 15. The Navy will drop its release score for doctors from 53 to 51 points on January 1. Navy dentists are released on the same scores as Navy line officers, who since November 1 have won discharge on 46 points. Surg. Gen. Norman T. Kirk reveals that he is pressing the War Department for speedier release of doctors and dentists. He is endeavoring to learn the minimum required overseas. General Kirk's office is also considering a recommendation that the Army cut its minimum discharge score to 10 points. At present the Army releases medical officers on 80 points or if they are 48 or had entered service before Pearl Harbor. Originally the Army had 45,000 medical men, and it expects to release 17,000 doctors and dentists by January 1. The rate of release is said to be faster than that for enlisted men. The Navy reveals that it is demobilizing three doctors to every thousand men, and, with 4,700 more doctors to be eligible soon, there are expected to be "few if any" doctors besides regular Navy doctors in service.

Senator Sheridan Downey, Democrat of California, endeavoring to learn how many doctors the Army is keeping in uniform, has asked the Surgeon General three questions: 1. What was the total troop enrolment and total number of doctors as of the first of every month from January 1945 through November? 2. Will you supply a list of all hospitals in the United States under the Surgeon General's command, together with the number of patients and doctors at each? 3. What is the total number of doctors assigned to the Veterans Administration?

"Almost a Million" Medical Examinations Given by Army

Two thousand service doctors and dentists in United States separation centers gave physical examinations to 572,119 outgoing Army men and women during the first twenty-four days of October. Additional service personnel received similar examinations from other doctors and dentists at other points, boosting the total number of examinations in the period to "almost a million." The physical examinations for discharge take about an hour. There are eight medical men available for each examination, the dischargee going to a dentist, an eye, ear, nose and throat specialist, an orthopedic surgeon for limb scrutiny, an internist for examination of the vital organs, a surgeon for study of scars, wounds or injuries, a laboratory man, and then a final check by an overall examiner, who may send the individual to a neuropsychiatrist for nerve tests. The Army revealed that medical school graduates are being commissioned and assigned as soon as they complete their internship. Most new medical men have been in the Army Student Training Program and are subject to immediate military assignment for the usual "duration and six months." All are assigned except those physically disqualified, the latter being reported as "relatively negligible."

Veterans Administration to Use AAF Hospital Planes

Army Air Forces hospital planes will be used by the Veterans Administration to fly patients from outlying hospitals to clinical centers. Previously patients have been moved by railroad, and long distances, particularly in Western areas, have been a serious handicap, but General Hawley, Veterans Acting Surgeon General, formerly Army chief surgeon in Europe, knows how air ambulances saved thousands of lives. Cooperation is expected from the AAF, which wants to keep a nominal number of hospital planes in operation. The agency will probably buy at least two hospital pullmans from surplus property stocks.

Further Changes in Veterans Administration

General Hawley is making an effort to use as many disabled veterans as possible in rehabilitation, prosthetics and other lines. The agency already has 123 disabled women veterans in training for its vocational rehabilitation program. The Nursing Advisory Council to the Administrator of Veterans Affairs has elected Ruth Sleepcr, R.N., assistant principal of the Massachusetts General Hospital, Boston, as its chairman and has recommended to General Hawley (1) the establishment of a nurse corps in the Veterans Administration, (2) continuation of the development of in-service training, (3) postgraduate educational programs for Veterans Administration nurses and (4) appointment of a nursing advisory committee to the nurse representative in the thirteen Veteran Administration branch offices.

General Omar N. Bradley, Veterans Administrator, has announced changes in agency terminology. He has banned the use of the word "facility" to describe veterans' hospitals, in the belief that a hospital is a hospital. A domiciliary facility will be known as a Veterans Administration home. A hospital or home to which a regional office is attached will be called a Veterans Administration center instead of a "combined facility," as it has been known up to now.

Army Tuberculosis Expert Lent to Veterans Administration

To assure a superior standard of care for tuberculous veterans, Col. Esmond Ray Long of Philadelphia, described as Army's number 1 man on tuberculosis, has been lent to the Veterans Administration, on request of Major Gen. Paul R. Hawley, acting surgeon general. Colonel Long, chief consultant on tuberculosis to the Surgeon General of the Army, explains that the war did not develop any new therapies in the treatment of tuberculosis. The Army has depended on the familiar methods of "collapse therapy," including pneumothorax treatment. He said that the incidence of tuberculosis in this war is only one tenth of first world war figures. In this war it was 1.2 per thousand men annually as against 12 cases per thousand men annually in the first world war. Colonel Long only recently returned from Germany, where he was attached to the Office of Military Government.

Hospitals Get First Call on Penicillin

Because of a three month production slump, the War Production Board moved to give hospitals first call on all production. There is also opinion in favor of restoring export controls to check the amount leaving the country. An emergency directive will remain in force until production increases. Production dropped from 688,890,000 billion units in July to 568,370,000 billion units in September. It started up again in October, reaching 612,470,000 billion units. Estimated production is 657,000,000 billion units in November and 657,960,000 in December.

Army Reveals Half of Personnel Inoculated Against Influenza

About half of the U. S. Army has received inoculations against influenza and the rest will get them soon. The first recipients in this country were the staff of Walter Reed Hospital, with Major Gen. Norman T. Kirk, Army Surgeon General, and Major Gen. George F. Lull, Deputy Surgeon General, and Major Gen. George F. Lull, Deputy Surgeon General, and Major Gen. George F. Lull, Deputy Surgeon General. The program is expected to among those taking their shots. The program is expected to be completed in a few weeks. All overseas men have received their inoculation.

Shortage of Penicillin as a Result of Public Demand

Public demand for penicillin in ointment or lozengc form is blamed for a nationwide shortage of the drug reported by the Food and Drug Administration. Dr. Henry Welch, chief of the penicillin division of the Federal Drug Administration, said that the shortage will be overcome in sixty days and will not affect hospitals or private physicians.

Three Million Red Cross Volunteers to Continue War Work

Mrs. Mason Colt, new national administrator of the National Red Cross Volunteer Special Services, announces that about three fourths of the 4,000,000 wartime volunteers plan to continue Red Cross work as a permanent community service. Her estimate was given following a four day conference in the Hotel Statler with 150 delegates from thirty-nine states. She said there will be plenty of work for peacetime volunteers, as hospital nurses' aides, in health clinics, in blood banks, in tuberculosis, eye and tooth clinics and as producers of bandages and surgical dressings for local hospitals. Mrs. Colt denies that socialites dominate the Red Cross and that the organization had refused to cooperate with other welfare workers.

Inadequate Pay Keeps Doctors from the Veterans Administration

Gen. Omar N. Bradley, Veterans Administrator, reveals that the agency is 1,300 doctors short of its 2,300 goal, largely because of disparity in pay. He says that unless the service is made more attractive to doctors the situation will become worse, as 570 lent by the Army and Navy are to be discharged and returned to private practice. In addition to better pay, General Bradley advocates (1) giving veterans doctors' recognition and (2) giving them a chance to improve and practice the most modern medicine. These were improvements in practice for Veterans Administration doctors which General Hawley, acting Surgeon General, said recently would be made.

Medicine and Food Dropped in New Cargo Bomb

How medicine and food can be dropped to communities cut off by flood, forest fire and other disasters was demonstrated at Bolling Field by the Army Air Forces when six wooden, snub-nosed "cargo bombs" were dropped at heights ranging from 200 to 1,000 feet. Two were dropped in water to show their buoyancy. The contents included rations, oil, gasoline, blood plasma, serums and first aid kits, all undamaged by the impact. The demonstration was staged for the American Red Cross in cooperation with the United States Steel Corporation, which developed the container with the Air Technical Service Command.

Council on Medical Service and Public Relations

PREPAID MEDICAL CARE NEWS

Latest on Prepayment Plans

Virginia.—The Virginia Medical Service Association, approved by the Virginia State Medical Society, is governed by a board of thirty-five persons, of whom not less than two thirds must be medical men. All administrative procedures are handled by the Blue Cross (Virginia Hospital Service Association). It is a combination indemnity-service plan with income limits for the latter set at \$2,000, \$2,500 and \$3,000. A single medical-surgical contract is issued. The medical coverage is limited to in-hospital cases of three days' or more duration and pays up to thirty-five days a year. A sum not to exceed \$10 a year is paid toward diagnostic x-ray in surgical cases. The surgical-obstetric coverage is similar to that of other society sponsored plans.

Maryland.—A plan has been drawn up and passed by the Maryland legislature. The details are now in the hands of Dr. Victor F. Cullen, State Sanatorium, Md.

Oklahoma.—The Oklahoma Physicians Service, approved by the Oklahoma State Medical Association, is now in operation throughout the state. There are fifteen trustees, of whom nine are doctors. The plan offers a surgical and obstetric indemnity contract with no medical provisions or riders.

Alabama.—The Alabama State Medical Association has turned to the Hospital Service Association (Blue Cross) of Alabama for medical-surgical coverage. The state laws were amended to enable the Hospital Service Corporation to provide medical and surgical contracts for its subscribers. The con-

tracts provide an indemnity only and include inpatient medical care (\$2 a day for twenty-five days), the usual surgical procedures and a number of additional in-hospital services not found in other plan contracts.

Arizona.—The governor of Arizona signed a bill on October 3, duly passed by the state legislature, entitled "the Arizona non-profit hospital and medical service corporation law." This enabling act differs from the enabling acts of most states in that it provides that the corporation may sell either hospital or medical service contracts or both. It also provides for service contracts only, without provisions for indemnity payments.

Washington.—The Washington State Medical Bureau has been instructed to prepare a statewide contract suitable to cover such organizations as the grange, small farmer groups and business concerns which operate over a wide territory. Consideration will be given to the necessity for a broader contract, for income limitations and to the eligibility requirements for such groups. The bureau was reorganized in April of this year to coordinate the various local Medical Service Corporations operating in this state. Mr. Ralph W. Neill is the bureau manager and Dr. John F. Christensen the president.

New York.—The house of delegates of the Medical Society of the State of New York adopted a resolution on October 9 urging the organization of a national casualty company to develop voluntary medical insurance coverage in areas where none exists and to enroll nationwide employers' groups.

Tentative plans call for a stock company owned and controlled by the medical profession. The company would assist medical society-sponsored plans through national enrolment of nationwide concerns. It would provide coverage in areas where it is not available and remain only until such time as the profession could set up its own plan. Hospital coverage would be offered through Blue Cross.

The Blue Cross hospital groups are already operating a plan along this same line. However, instead of a new corporation, a central enrolment office has been organized with headquarters in New York. This office will service all eighty-seven Blue Cross Plans and merely act as agent for them.

Genesee Valley Prepayment Plan

Rochester physicians have officially approved a prepayment medical care plan to start operations on Jan. 1, 1946. The announcement was made by Mr. George P. Farrell, director of the Bureau of Medical Care Insurance of the Medical Society of New York.

The plan, Genesee Valley Medical Expense Indemnity Inc., is fully organized and awaits only the approval of the State Department of Social Welfare. It has its own trustees and will offer a limited surgical and obstetric contract until sufficient experience is gained to allow increased benefits.

Administrative service such as enrolment, billing and record keeping will be provided by the Rochester Hospital Service Association. The charge will be based on cost. All policies relating to the medical care plan will be determined by the Genesee Valley Medical Expense Indemnity Inc.

Coming Medical Meetings

American Medical Association House of Delegates, Chicago, Dec. 3-6. Dr. Olin West, 535 N. Dearborn St., Chicago 10, Secretary.

American Academy of Allergy, Chicago, Dec. 10-11. Dr. Karl D. Figley, 316 Michigan St., Toledo 2, Ohio, Secretary.

American Association on Mental Deficiency, Cleveland, Nov. 28-Dec. 1. Dr. Neil A. Dayton, Box 51, Mansfield Depot, Conn., Secretary.

American Society of Anesthetists, New York, Dec. 12-13. Dr. McKinnie L. Phelps, 745 Fifth Ave., New York 22, Secretary.

International College of Surgeons, U. S. Chapter, Washington, D. C., Dec. 7-8. Dr. Louis J. Gariepy, 16401 Grand River Avenue, Detroit, Secretary.

North Pacific Pediatric Society, Portland, Ore., Dec. 1. Dr. Aldis B. Johnson, Cobb Bldg., Seattle 1, Washington, Secretary.

Oklahoma City Clinical Society, Oklahoma City, Nov. 26-29. Dr. Elmer R. Musiek, 512 Medical Arts Bldg., Oklahoma City, Secretary.

Puerto Rico Medical Association of, San Juan, Dec. 14-16. Dr. Rafael A. Vilar, P. O. Box 3866, Santurce, Secretary.

Southern Surgical Association, Hot Springs, Va., Dec. 4-6. Dr. Alfred Blalock, Johns Hopkins Hospital, Baltimore 5, Secretary.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Neuropathologist for Langley Porter Clinic.—Dr. Nathan Malamud, Ann Arbor, Mich., has been appointed neuropathologist at the Langley Porter Clinic and associate clinical professor of psychiatry at the University of California Medical School, San Francisco. According to the University of California *Clip Sheet*, while an excellent neuropathologic laboratory was constructed when the clinic was built, this is the first appointment of a neuropathologist, which, it is expected, will further the plans to attack the problem of mental disease from every angle. Neuropathologic material will be received from all the state hospitals, states the *Clip Sheet*. The Langley Porter Clinic will not only be coordinated with the medical school of the university but will be the focus for these studies for the state hospital system, thus enabling the clinic to enlarge its service to the state. Dr. Malamud graduated at McGill University Faculty of Medicine, Montreal, in 1930.

New Medical School Planned.—Plans for the establishment of a new medical school in Los Angeles were under way October 29 following action of the regents of the University of California authorizing Robert G. Sproul, president, Berkeley, to seek funds from the state legislature for the purpose. Recognizing the need for additional facilities in the southern part of the state, the regents unanimously approved a recommendation to provide full training in medicine in connection with the Los Angeles campus of the university. Only one third of the doctors needed annually in southern California can be trained by the existing medical school there, according to the University of California *Clip Sheet*. University officials estimated that some sixty students would receive instruction in the new school each year, which would nearly equal the present facilities of the university on the San Francisco campus. Depending on action by the legislature, it may be from two to three years before the full curriculum can be offered in medicine, but lower division work may begin within a year, officials said.

COLORADO

Plan Medical Research Center.—Establishment of a major medical research center in Denver as a cooperative venture of the University of Colorado School of Medicine, Denver, the University of Denver and other institutions is now being considered, according to a statement to the press by Robert L. Stearns, LL.D., president of the University of Colorado. One branch would be designed to further medical science and improve public health in the area and would be operated in connection with the Colorado medical school and the Colorado General Hospital.

INDIANA

John N. Hurty Service Award.—The Indiana State Board of Health has created the John N. Hurty service award to honor the late physician who was secretary of the board from 1896 to 1922. Presented for the first time this year, the award was given to about 150 state employees who have been connected with water supplies and who have served twenty-five years or more. In this particular award Dr. Hurty is being honored for his efforts to organize the Indiana section of the American Water Works Association, which he served as president for two consecutive years.

State Medical Election.—Dr. Floyd T. Romberger, Lafayette, was chosen president-elect of the Indiana State Medical Association during its annual meeting in French Lick, November 6-8. Dr. Jesse E. Ferrell, Fortville, was installed as president. Dr. George R. Dillinger, French Lick, resigned as delegate. Dr. Alfred S. Giordano, South Bend, was elected delegate to the 1945 session of the House of Delegates of the American Medical Association and Dr. Don F. Cameron, Fort Wayne, was reelected delegate. Other delegates include Drs. Franklin S. Crockett, Lafayette, and Homer G. Haner, Indianapolis. The 1946 meeting of the state association will be held in Fort Wayne.

MASSACHUSETTS

Lectures on Epilepsy.—Dr. William G. Lennox, Boston, opened a series of six free lectures on "Epilepsy, the Hopeful Disorder," November 15. The lectures are being given on Thursdays at the Boston Public Library under the auspices of the Lowell Institute.

Civilian Blood Program for Massachusetts.—The Massachusetts Department of Public Health will soon begin distribution of blood plasma and other blood products without cost on the same basis as serums and vaccines. The service, which is to be available to the citizens of the state, will operate as a unit of the division of biologic laboratories. The legislature has appropriated \$174,000 to equip, staff and operate a blood and blood derivatives program, and the Godfrey M. Hyams Trust of Boston has donated \$176,000 to Harvard University to construct a modern well equipped laboratory building in which processing and fractionation of blood and its products can be carried out as well as other essential procedures. The project will include collection of blood donations as donor programs are organized by civic or other groups in various communities; processing of the blood to the various fractions of known value, such as plasma, albumin, gamma globulin, fibrin foam, fibrin film, blood grouping serums and other fractions still in the process of development, as well as resuspended red cells and whole blood as soon as suitable methods for their preservation are established, and distribution of these products through recognized channels and in accordance with community contribution of blood donations.

MICHIGAN

Foundation for Medical and Health Education.—On September 19 the Michigan Foundation for Medical and Health Education, sponsored by the Michigan State Medical Society, was incorporated. Purposes of the foundation are to "acquire, provide, use, develop, endow and finance methods, means and facilities for postgraduate education in medicine, for education in medicine, for lay health education and for research, fellowships and scholarships." Officers of the foundation include Dr. Earl I. Carr, Lansing, president; Dr. Burton R. Corbus, Grand Rapids, vice president, and Herbert H. Gardner, president of the Birmingham National Bank, treasurer. William J. Burns, LL.B., Lansing, executive secretary of the state medical society, is secretary. In an effort to expedite and reach the goal of \$150,000 within a year, Dr. Arthur S. Brunk, Detroit, retiring president of the society, offered in September to contribute the sum of \$1,000 to the foundation provided ninety-nine members of the society contribute a like sum during the next twelve month period. This proposed \$100,000 would be added to the state society's contribution of \$10,000 and that of the late Dr. and Mrs. Arthur P. Biddle, about \$40,000, to make the total by September 1946 of \$150,000, the income of which would be available for immediate postgraduate needs. With the \$33,000 subscribed within a month of this offer, the foundation on October 23 had \$83,000. The Biddle bequest in 1944 was added to the \$10,000 fund of the state society, which in 1942 established a graduate education program to stimulate postgraduate work among practicing physicians (*THE JOURNAL*, Aug. 15, 1942, p. 1380; Oct. 28, 1944, p. 578). Credit goes to Dr. Corbus, Dr. Carr and Dr. James D. Bruce, Ann Arbor, for establishing the new foundation.

NEW YORK

Experimental Test of Ultraviolet Rays in Children's Diseases.—The village of Pleasantville was recently chosen for the first communitywide test in the nation of the use of ultraviolet rays to disinfect air inhaled by school children. Beginning January 1 and continuing for three years, ultraviolet lamps will be used in all classrooms of the high school and two grammar schools of Pleasantville. Tentative arrangements have been made to install similar lamps in the motion picture theater, the six churches and other buildings where children congregate. The project is sponsored by the Westchester County Health Department, of which Dr. William A. Holla is director, the Milbank Memorial Fund of New York, the University of Pennsylvania School of Medicine, Philadelphia, and the General Electric Company. According to the *Bulletin* of the Medical Society of the County of Erie and the Buffalo Academy of Medicine, the experiments will provide radiant disinfection of air, with lamps concealed so as not to cast rays directly on the children. The *Bulletin* states that for the last nine years similar experiments have been conducted

in certain schools of Pennsylvania and adjacent states. The experiments are intended to destroy germs that cause measles, mumps, chickenpox, virus pneumonia and common colds, but little effect was anticipated in checking infantile paralysis.

Urges Reconstitution of State Medical Commission.—The house of delegates of the Medical Society of the State of New York, at its recent meeting, adopted a resolution requesting the governor "to reconstitute the New York State Commission on Medical Care by the appointment of additional active practitioners of medicine." It was also voted to request the governor's commission to "provide for a continuing conference with representatives of the society" in order that a plan may eventually be developed which will accomplish the declared objectives of the governor's charge to his own commission. The state society believes that "the tentative plans developed by this commission, as revealed recently to representatives of the Medical Society of the State of New York, contain many proposals and features which, in their judgment, are unpractical and would prove detrimental to sound medical progress and would effectually destroy the integrity and freedom of the medical profession." This last phrase has reference to the governor's charge to this commission, namely that it devise "a workable plan for broadening the availability of medical services and hospitals while at the same time preserving the integrity and freedom of the medical profession." The society also contends that this commission, as at present constituted, "contains an inadequate number of physicians who truly represent the general practice of medicine."

New York City

Spanish Speaking Association Plans Congress.—The International and Spanish Speaking Association of Physicians, Dentists and Pharmacists is making plans for a postwar Latin American congress, according to the secretary, Dr. Ernest F. Dupre. Dr. Jacob M. Gershberg, president, recently returned from a trip to Mexico, Central America and San Francisco during which he added seven new chapters, bringing the total of such units in the association to forty-nine.

Meeting of Society to Study Blood.—The recently formed Society for the Study of Blood met at the New York Academy of Medicine November 8 to hear the following speakers: Drs. John T. Edsall, Boston, on "The Antihemophilic Globulin of Normal Plasma," Louis K. Diamond, Boston, "The Clinical Use of an Antihemophilic Fraction of Blood Plasma," and Randolph West, New York, and Erwin Chargaff, Ph.D., New York, "Hemophilic Clotting Defect in a Female." The society was formed at a meeting June 14 (THE JOURNAL, July 21, p. 893).

Clinical Aspects of Visceral Insufficiency.—Members of the staff of Mount Sinai Hospital are offering a series of lectures on "The Clinical Aspect of Visceral Insufficiency." The series follows:

- Dr. Eli Moschowitz, November 28, Intestinal Insufficiency. The Sprue Syndrome.
- Dr. Ernst P. Boas, December 12, Myocardial Insufficiency.
- Dr. Charles K. Friedberg, December 26, Peripheral Circulatory Insufficiency.
- Dr. Arthur M. Fishberg, January 9, Renal Insufficiency.
- Dr. Benjamin Eliasoph, January 23, Thyroid Insufficiency.
- Dr. Coleman B. Rubin, February 6, Respiratory Insufficiency.
- Dr. Isidore Snapper, February 20, Parathyroid Insufficiency and Osseous Disease.
- Dr. Louis J. Soffer, March 6, Adrenal Insufficiency.
- Dr. Henry Dolger, March 20, Pancreatic Insufficiency.
- Dr. Solomon S. Lichtman, April 3, Hepatic Insufficiency: Metabolic Aspects.
- Dr. Joseph H. Gléms, April 17, Pituitary Insufficiency.

OHIO

Training for Returned Service Physicians.—Western Reserve University School of Medicine, the Academy of Medicine of Cleveland and eighteen hospitals, comprising the Cleveland Hospital Council, will cooperate in providing special training for three different groups of doctors in need of refresher courses. The first phase of the program will be handled by individual hospitals, while additional internships and residencies will be provided within the capacities of the clinical facilities at each. The second phase of the overall program has been developed for ex-army and navy physicians who have completed two or more years of hospital training, with the medical school offering a three month refresher course covering fields of medicine, pediatrics and general surgery. Students may enroll in the refresher course on the first of any month in which there is a vacancy. The program will include a series of seminars in various topics, with free time allowed for reading and consultation with members of the staff. The third phase of the program is a "graduate fort-

night" for both former military medical officers and the civilian doctor who has been too hard pressed during the war years to keep up with latest developments. This is under a special committee of the academy of medicine.

OREGON

Changes in Health Officers.—Dr. Robert W. Ripley has resigned as health officer of Corvallis to accept a position in the Connecticut State Department of Health. Dr. William T. Edmundson, Newberg, has been appointed health officer for Hood River County, effective August 1, to succeed Dr. Cecil W. McCain, Hood River, resigned.

New Director of Industrial Hygiene.—Dr. Charles M. McGill, New Orleans, surgeon, U. S. Public Health Service, has been appointed director of the industrial hygiene division of the Oregon State board of health, effective October 1. Dr. Thomas F. Mancuso, Portland, who has been acting director, has been assigned to a similar position with the Ohio State Health Department, according to the Portland Journal, September 12.

PENNSYLVANIA

Graduate Assembly.—The Harrisburg Academy of Medicine will sponsor a postgraduate assembly November 29. The following members of the staff of Harvard Medical School, Boston, will participate: Dr. Charles A. Janeway, assistant professor of pediatrics, Dr. Lewis Dexter, instructor in medicine, and Dr. Sinclair Armstrong, instructor in medicine and research associate in physical chemistry.

Philadelphia

Schireson Injunction Against State Board Dissolved.—The injunction restraining the Pennsylvania State Board of Medical Education and Licensure from revoking the license of Henry Junius Schireson, allegedly obtained by fraud, was dissolved by Judge Karl E. Richards in the court of common pleas of Dauphin County, November 2. Through this action the court upheld the contention of attorneys for the board that a state licensing body had "the inherent right to revoke a license obtained by fraud." The court also refused to accept the plaintiff's contention that the board was guilty of laches in attempting to revoke a license which had been issued some thirty years earlier. In explaining the latter decision the court pointed out that the mere passage of time is not a criterion in determining the guilt of laches. Since the record did not disclose when the board became aware of the fraudulent aspect of the license, the court could not find any basis for holding the board guilty of laches. On June 29, 1910 Schireson was issued a license authorizing him to practice medicine and surgery in the state. Under this license he practiced in Pennsylvania from 1910 to 1913 and again from 1932 to the present time. On June 30, 1944 the state board of medical education and licensure issued a citation to Schireson requiring him to show cause why his license should not be revoked for alleged fraud, misrepresentation and deception practiced by him in procuring his license. Before the time set for hearing on the citation, Schireson filed a bill of complaint seeking to restrain the board from proceeding thereon. A preliminary injunction was granted, which by consent of the parties had been continued to the recent hearing.

VIRGINIA

Personal.—Dr. James N. Dudley, for some time health officer for the Southside Health District with headquarters at Farmville, has been appointed health officer for the city of Newport News; he was to have assumed office on October 1. He succeeds Dr. William Y. Garrett, Eastville, who resigned because of his health.—Dr. Thomas D. Walker Jr., Newport News, has been appointed city physician of Newport News to succeed Dr. Louis Loeb, retired.—Dr. Albert T. Brickhouse, health officer of Hopewell, has been appointed city coroner to fill the unexpired term of Dr. Johannes C. Bodow, resigned, it is reported. Dr. Brickhouse will serve until Dec. 31, 1947.

State Medical Election.—Dr. William L. Powell, Roanoke, was made president-elect of the Medical Society of Virginia at its meeting in Roanoke October 23. Dr. Julian L. Rawls, Norfolk, was installed as president. Other officers include Drs. James D. Hagood, Clover, William L. Peple, Richmond, and Walter C. Caudill, Pearisburg, vice presidents. Miss Agnes V. Edwards, Richmond, was reelected secretary. The society voted to hold its 1946 meeting at Virginia Beach in October. Dr. Henry B. Mulholland, Charlottesville, retiring president of the society, was named delegate to the American Medical Association.

WASHINGTON

Bubonic Plague in Tacoma.—The city of Tacoma is said to be again "free of plague infection" through a concerted program of rodent control. During the past three years the port of Tacoma has been in quarantine about twenty-one months and in this period has been quarantined and reopened twice (*THE JOURNAL*, January 6, p. 46). According to *Northwest Medicine* the statement "free of plague infection" came from the U. S. Public Health Service, and control of the disease is again in "the hands of Tacoma."

Personal.—Dr. Ann P. Kent, Washington, D. C., has joined the staff of the Territorial Department of Health as field physician in charge aboard the mobile health unit vessel *Hygiene*.—Dr. Edward L. Van Aelstyn, Price, Utah, has been appointed director of the Cowhitz and Wabikakum counties health departments, succeeding Dr. Thomas H. Biggs, Kelso, who resigned recently to devote his time to private practice.—Dr. Walter M. Morgan has been named health officer of Kent, succeeding Dr. George M. MacGregor, who resigned June 1.

Emily Pratt Named Head of New Hearing Section.—Dr. Emily A. Pratt, Albany, N. Y., who was appointed as otologist with the Washington State Department of Health, October 1, will be the head of the newly created Conservation of Hearing Section. Dr. Pratt, who has had years of successful experience in developing services for hard of hearing children in New York, will intensify the program now being conducted for school children in the state of Washington. This work will be carried out in cooperation with the department of public instruction and will fulfill the provisions of the law passed at the last session of the state legislature.

WEST VIRGINIA

Personal.—The following physicians were recently elected to honorary life membership in the West Virginia State Medical Association: Drs. Charles M. Hanes, Huntington, Raymond M. Sloan, Huntington, Henry E. Baum, Charleston, Wilbert G. Drinkwater, Gorman, and Jesse O. Barliff, Mullens.

Cancer Field Worker Appointed.—Miss Frances Meyer, Charleston, has been appointed cancer field worker for Kanawha County under the sponsorship of the local chapter of the Field Army of the American Cancer Society. The project, which is the first of its kind to be undertaken by the Field Army in West Virginia, will be paid for from funds raised during the 1945 cancer drive. Miss Meyer, who is experienced in the field of public welfare, will do follow-up work with needy cancer patients to make sure that they return to their doctors for follow-up examinations. She will cooperate with and aid city and county health nurses, the health department and the local department of public assistance to utilize all services available for obtaining care for needy cancer patients.

State Association Plans New Home.—Initial steps looking toward the construction of a permanent home for the West Virginia State Medical Association were taken by the council at a meeting at Parkersburg, October 14. The council directed the president, Dr. Thomas L. Harris, Parkersburg, to appoint a committee to confer on the subject with a similar committee from the Kanawha Medical Society. Recognizing the need for the extension of medical care to outlying districts in the state, the council directed the president to appoint a committee on rural medical service to work with committees of the American Farm Bureau Federation and other farm organizations planning rural health improvement. Besides approving revisions by the Public Health Council of regulations concerning the control of communicable diseases, the council recommended the adoption in principle by that body, as the official communicable disease code for West Virginia, of the American Public Health Association's manual on "The Control of Communicable Diseases."

WISCONSIN

Surgical Meeting.—The Wisconsin Academy of Surgery held a joint meeting with the Jackson Clinic Post-Graduate Group at Madison, October 18-20. Among the speakers were

Dr. George H. Euell, Madison, Polycystic Kidney
Drs. R. and Arnold S. Jackson, Madison,
The Disease
Drs. L. and James A. Jackson, Madison,
The
Dr. Arthur C. Stirling, Madison, Ruptured Intervertebral Disk
Dr. Donald L. Dickerson, Draville, Ill., Penicillin and Streptomycin
in Surgery
Dr. Luther J. Holmgren, Madison, The Hernia Problem

A special lecture was given by Dr. Warren H. Cole, Chicago, on "Treatment of Surgical Lesions of the Stomach Including Preoperative and Postoperative Care."

GENERAL

New Journal on Geriatrics.—The new bimonthly medical journal *Geriatrics*, devoted to research and clinical reports on the processes and the diseases of the aged and aging, will appear in January. Modern Medicine Publications announced. The editor will be Dr. Axel E. Hedback, Minneapolis.

Luzier Grant for Work in Dermatologic Allergy.—The American College of Allergists announces a recent grant of \$1,500 to the college to be used for a research fellowship from Luzier's, Inc., Kansas City, Mo. The grant is to be known as the Luzier Grant for Fundamental Investigation in the Field of Dermatologic Allergy. The fellowship will be under the direction of Drs. Rudolf L. Baci, New York, and Stephan Epstein, Marshfield, Wis.

Cancer Society Opens Midwest Branch.—Mr. George B. Larson, formerly assistant secretary of the Wisconsin State Medical Society and for the past year associated with the Field Army of the American Cancer Society, has been named Midwest Field Army director in charge of a new midwest branch to be opened in Suite 1512 of the Marshall Field and Company Annex Building, 25 East Washington Street, Chicago. The new office will supervise the states of Illinois, Indiana, Iowa, Michigan, Minnesota, Missouri, Wisconsin, Kansas and Arkansas.

Allergy Meeting.—The American Academy of Allergy will hold its second annual meeting at the Palmer House, Chicago, December 10-11, under the presidency of Dr. Oscar Swineford Jr., Charlottesville, Va., who will discuss undergraduate education in allergy. Among the speakers will be

Drs. Harold D. Dundy, Benjamin Zohn and Robert Chobot, all of New York. Chemical Evaluation of Histamine Azoprotein
Dr. Albert V. Stoecker, Minneapolis, Influence of Soy Bean Products on the Plasma Lipids and the Course of Eczema
Dr. John M. Robinson, Houston, Texas, Physiology and Functional Pathology of the Lymphatic System Applied to Allergy of the Nose and Paranasal Sinuses
Dr. Freda Brumman, Dr. Fern Crump, Dr. Floyd D. Seeger, Dr. Ann Catherine Arthurs and Ruth E. Miller, Ph.D., all of Philadelphia, Use of Oral Penicillin in Treatment of Intermittent Asthma

The program will also include a symposium on infectious asthma and one on antihistamine and autanaphylactic drugs.

Advisory Health Group Meeting.—Prompt action in the development of an international health organization was urged by thirty leaders in public health and civic activities at a meeting held in the Department of State, Washington, D. C., October 11-12 on an advisory health group called by the department under the chairmanship of Dr. Thomas Parran, Surgeon General, U. S. Public Health Service. The group recommended that the U. S. government associate itself immediately with other nations in taking steps leading to the early formation of a new and broad international health organization to be closely linked with the Economic and Social Council of the United Nations. Certain general functions visualized for the organization are the collection and analysis of worldwide disease statistics as a basis for epidemic control, assistance to national health services to control disease at their sources, centralization, consolidation and subsequent distribution of health and medical knowledge and the standardization and control of drugs and other therapeutic agents.

Five Years of Rehabilitating Asthmatic Children.—The National Home for Jewish Children at Denver has for the past five years been caring for underprivileged children suffering from acute bronchial asthma and other refractory upper respiratory diseases. The home is located in Denver and is available to children from all over the country whose families cannot afford extensive and costly private care. The children remain until physicians recommend that they be returned to their homes in a comparatively normal environment, and during the companionship of other children, the asthmatic child is under expert medical supervision at the home and is cured for by a staff trained in child welfare. During his stay, periodic examinations are made and full reports given to the referring physicians and hospital clinics. The National Home has a modern, well equipped infirmary where children requiring bed care are attended by registered nurses under the supervision of the attending physicians. The children are housed in attractively furnished congregate cottages with individual bedrooms. Food of the highest quality is carefully prepared by physicians. The children participate in the community life by attending the local schools and taking part in communal recreations. In addition to the intensive preparation made prior to the child's admission to the home, an equally thorough after-care program

is carried out on the return of the child to his family. The aim of the program is to make certain that the child will continue to enjoy his restored health in the very environment which originally was a factor contributing to the child's illness. Trained social workers educate the parents to the general health practices which play an important part in the treatment of allergic diseases. Application may be made by communicating with the Social Service Department of the National Home for Jewish Children at 1457 Broadway, New York 18, or through the office of the Jewish Social Service organization in any community.

Southern Surgical Meeting.—The fifty-seventh annual meeting of the Southern Surgical Association will be held at The Homestead, Hot Springs, Va., December 4-6 under the presidency of Dr. Charles A. Vance, Lexington, Ky., whose subject will be "The Transylvania Medical Library." Among the speakers on the program will be:

Dr. William P. Longmire Jr., Sapulpa, Okla., and Major Marcus M. Ravitch, M. C., Baltimore, A New Method for Constructing an Artificial Esophagus.
Major Robert P. Kelly, M. C., Capt. Louis M. Rosati, M. C., and Capt. Robert A. Murray, M. C., White Sulphur Springs, W. Va., Treatment of Traumatic Osteomyelitis.
Col. Daniel C. Elkin, M. C., White Sulphur Springs, Cirroid Aneurysm of the Scalp.
Major Boris P. Petroff, M. C., Martinsburg, W. Va., Streptomycin in Treatment of Urinary Infections.
Drs. Charles S. Venable and Walter G. Stuck, San Antonio, Texas, Muscle Implant in the Treatment of Monarticular Hypertrophic Arthritis of the Hip (Destructive Arthritis, Aseptic Necrosis and Other Conditions).
Dr. J. Albert Key, St. Louis, Bunnell's Pull Out Wire Sutures for the Fixation of Tendons, Both as Grafts and as Transplants.
Lieut. Col. Brian B. Blades, M. C., Washington, D. C., Mediastinal Tumors: A Report of Cases Treated at Army Thoracic Surgery Centers in the United States.
Dr. Guy L. Hunner, Baltimore, Is Ureteral Stricture an Etiologic Factor in the Genesis of Renal Tumor?

One feature will be a symposium on "Newer Concepts in the Treatment of the Paralyzed Patient Due to Wartime Injuries of the Spinal Cord."

Fellowships in the Medical Sciences.—Fellowships in the Medical Sciences, similar to those which have been administered by the Medical Fellowship Board of the National Research Council since 1922, will again be available for the year beginning July 1, 1946. These fellowships, supported by grants from the Rockefeller Foundation to the National Research Council, are designed to provide opportunities for training and experience in research in all branches of medical science. They are open to citizens of the United States or Canada who possess an M.D. or a Ph.D. degree and are intended for recent graduates who are not yet professionally established. In addition to these fellowships the medical fellowship board administers two groups of research fellowships, made available through a grant from the National Foundation for Infantile Paralysis, Inc. The first group, open to applicants who hold either the Ph.D. or the M.D. degree, is for the purpose of providing opportunities for special training and experience in the study of filtrable viruses. The second group, open only to graduates in medicine who have completed one or more years of hospital experience in clinical surgery and are planning a career in orthopedic surgery, is designed to provide opportunities for training and research in those basic medical sciences which will be of particular value in furthering progress in the field of orthopedic surgery. A series of fellowships in anesthesiology has been established through a grant from the American Society of Anesthesiologists. These fellowships are offered with a view to fostering a closer union between the clinical practice of anesthesiology and the fundamental disciplines on which anesthesia rests. Applicants must hold the M.D. degree and must have completed one or more years of hospital experience as intern or resident. Fellows will be appointed at a meeting of the Medical Fellowship Board late in February 1946. Applications to receive consideration at this meeting must be filed on or before January 1. Appointments may begin on any date determined by the board. For further particulars concerning these fellowships, address the Secretary of the Medical Fellowship Board, National Research Council, 2101 Constitution Avenue, Washington 25, D. C.

CORRECTION

Incorrect Affiliation.—Mr. Irvin R. Vaughn is director of the division of public health education and assistant director of the division of vital statistics of the South Dakota State Board of Health. THE JOURNAL, September 29, page 367, in its Organization Section, referred to Mr. Vaughn as being affiliated with the North Dakota State Health Department.

Government Services

Memorial Laboratory of Infectious Disease

Construction has started on a new infectious disease laboratory of the National Institute of Health, U. S. Public Health Service, and the Federal Security Agency. The building is located in Bethesda, Md., and will be known as the Memorial Laboratory of Infectious Diseases of the United States Public Health Service, in tribute to the laboratory workers of the service who died as a result of risks involved in their professional duties. New methods of control are to be employed. Forced ventilation, with pressure control of air intake and output, will be a major factor of protection. The correct placement of air vents and the control of air volumes and velocities are intended to insure a safe air supply. Air currents so controlled will provide escape for infectious matter in the air. Moreover, contaminated air will be purified by being drawn by fans through protective fluclike hoods. The hoods will contain electric grills that will automatically incinerate infectious particles. Automatic mechanisms which will not operate until sealed are additional safety innovations that will be used on high speed equipment. These machines will also be flooded with ultraviolet light. Workers will leave and enter the laboratories through "decontamination chambers." These chambers will be divided into three sections, a dressing room for street clothes, a shower room and another dressing room for laboratory clothes. Special mirror arrangements will be installed so that workers can thoroughly inspect themselves. The entire building will be sprayed with DDT, and

Infectious Disease Laboratory.

there are to be six separate self-contained units in two wings, which will be separated by a main hall, on which the clerical offices and library will open. These units will be dedicated to the individual study of infectious diseases. Each unit will contain a small laboratory room for chemical and serologic work and a larger room containing three small glass enclosed cubicles for the cultivation of the infectious agent. Unit laboratories will have special equipment rooms. In addition, the units will contain three animal rooms—one for large animals and the remaining two to house the small laboratory animals. Plans also call for a necropsy room, a hot and cold temperature room and a sterilization chamber. The units are to be wholly self contained and completely independent. Each will have its own dumbwaiter, which will connect directly with the incinerator. With an overall floor space of 9,626 feet, the three story building will be approximately 185 feet long and 48 feet wide. The interior is to be tile surfaced and of "flush" construction. All pipes, shelves, cabinets and lights are to be built into the walls and ceilings to facilitate cleaning and sanitation. The exterior will be finished in red brick to conform with the other six buildings located on the 97 acres of land of the U. S. Public Health Service. The original sum needed for the construction of the building was obtained by the public health service from the Public Building Administration with the approval of the Bureau of the Budget. While some of the equipment will be purchased out of annual funds of the National Institute of Health, it may be necessary, in order to equip the building completely, to secure additional funds. Present plans call for the completion of the building around May 1946. It is planned to open it for public inspection for two weeks, after which time the only visitors permitted entry will be scientists.

The Disabled Persons Register

The measures taken by the government for the benefit of the disabled are on a scale never before attempted and are most thorough. An important new feature is the register of disabled persons entitled to the advantages provided by the Disabled Persons Employment Act. Persons disabled through war service, through industrial, road or other accident or congenitally disabled are entitled to register. Disablement due to disease is recognized equally with disablement caused by wounds or injury. Thus individuals who do not qualify for war disability pensions come within the scope of the act.

There are three principal benefits: (1) courses of vocational training and industrial rehabilitation for those who need to learn a new profession, trade or occupation or who require a special course to return to work after hospital treatment for injury or sickness, (2) assistance toward ordinary employment through requiring employers to engage an indicated proportion of disabled persons and (3) employment under special or sheltered conditions for the more severely disabled, who could not obtain work in competitive employment.

Registration is voluntary and its one purpose is to obtain a list of identifiable disabled persons. When this attains any size the minister of labor will fix the quota of disabled persons whom every employer of more than thirty persons must engage. To begin with, the quota will probably be 2 per cent, and as the register grows so also will the quota. It is expected that the register will grow to a million.

German Losses in the War 7,400,000

In the House of Commons the prime minister, Mr. Atlee, stated that the estimated total losses of the German armed forces in killed, permanently wounded and permanent medical casualties were 7,400,000. This is in striking contrast to the total losses of the British commonwealth and empire forces, which amounted to 1,233,796, of whom 336,772 were killed. This total includes 330,523 prisoners of war and covers the period from Sept. 3, 1939 to May 31, 1945.

In the war of 1914-1918 the British losses were much greater. The British total losses amounted to 3,285,090, of whom 966,230 were killed. The German losses were 6,252,494, of whom 2,050,466 were killed. The greatly reduced British casualties in the second and greater war may be explained by the greater amount of fighting on the Russian front than in the previous war and the excellent arrangements for the crushing of Germany on the western front. The artificial harbor for the landing on the Normandy coast, which was prepared in secrecy, came as a complete surprise to the German high command, who, with characteristic thoroughness, did everything possible to render impregnable the places where they thought a landing might be attempted. This device alone probably saved hundreds of thousands of casualties.

**Total Prohibition of Opium in the Far East
by the British Government**

The total prohibition of opium in Malaya and all British protected countries in the Far East is announced by the British military administration in Singapore. This takes the place of the policy of Malaya before the war of gradually reducing government revenue from opium with total prohibition as the goal. The success of the new policy will depend on effective control of opium production in other countries. The British government is therefore consulting with other governments to secure cooperation.

Oct. 26, 1945.

Franco-Swiss Medical Week

A Franco-Swiss Medical Week, organized under the auspices of the Swiss Academy for Medical Sciences, has just ended. It held its meetings in the University of Geneva. With profound emotion the Swiss medical group received 120 doctors from France. This was the first official contact between medical people of France and Switzerland since the armistice of 1940. Among the French guests were Professor Roussy, rector of the University of Paris, Professor Courrier of the Institut de France, Professor Brouardel, president of the French Medical Academy, Professor Brocq, secretary of the French Surgical Academy, Professor Cornil, Professor Mondor, Professor Baudoin, dean of the Medical College of the Paris University, Professor Hermann, dean of the Medical College of the University of Lyons, and Dr. Cavaillon, general secretary of the Ministry of Public Health.

Professor Wegelin, president of the Swiss Academy of Medical Sciences, received the French guests at the official opening, where Messrs. Etter, minister for home affairs, Lachenal, Hoppenot, French ambassador in Switzerland, Professor Babel, rector of the University of Geneva, and Professor Bickel, dean of the Medical College of the same university were also present. Professor Roussy, rector of the University of Paris, and of Swiss origin, received the title of Doctor honoris causa of the University of Lausanne, together with Professor Charles Lenormand.

Tropical Institute in Basle

Thanks in part to facilities provided by the American authorities, a scientific expedition has left the Swiss Institute for Tropical Sciences in Basle for Leopoldville in the Belgian Congo, West Africa. This expedition aims to prepare for the hospitalization in Switzerland of patients suffering from tropical diseases. The mission, which includes Professor R. Geigy, director of the institute, Professor F. Rouet of the Pathologic Institute in Basle and Dr. H. Gashen of the Institute for Hygiene in Lausanne, will collect medical and entomologic data on tropical diseases, the causes and the agents through which they are transmitted and other data which will serve for research work and lectures at the Tropical Institute. The mission will remain some four months and then return to Switzerland.

Professor Mazel in Switzerland

Professor Mazel, director of the Institute of Forensic Medicine at the Medical College of Lyons, spoke at Geneva and Lausanne concerning the German occupation in the Lyons area and its medical consequences. Professor Mazel, a personal victim of the Nazis, as he was imprisoned in the Fort de Montluc, described with great dignity and perfect scientific objectivity the sufferings of Lyons and France. The practice of medicine during the occupation was difficult not only because of the lack of materials but because the occupation itself was trying particularly when health certificates had to be delivered for the exiled workers in Germany. It became even more difficult when the doctors were ordered to give to the Pétain authorities the names of people wounded by bullets; it was not in accord with professional ethics and it meant that people in the resistance movement would be arrested. Fortunately the National Council of the Order of Doctors intervened and that order was revoked.

Professor Mazel said that the only good things resulting from the occupation was the decrease of alcoholism and crime. This was due to the difficulty of obtaining alcoholic drinks and to the fact that most of the young people had gone to Germany or to the Maquis. On the other hand, criminal acts by boys

and girls, such as thefts and delicts due to disorganization of the family increased. The same applies to political criminality. Professor Mazel had been officially appointed to make an inquiry into the crimes committed by the Nazis in the Lyons area.

American Doctors in Switzerland

An officer from the headquarters of General Eisenhower is considering with Swiss authorities the possibility of students in uniform studying in Switzerland. About 150 doctors and nurses would come for one or two weeks to visit Swiss hospitals and sanatoriums. Lectures during one to two or three months would also be organized in the different medical colleges for 2,500 students.

GERMANY

The following medical news has been obtained through the Department of Commerce, Washington, D. C.—EDITOR.

Work Being Done at the University of Munich Medical School

The pharmacology department had an enrolment of 400 to 600 students per semester in normal times. The last instruction period ended about March 1, 1945, but previous damage to the buildings and equipment prevented practical work from being carried out during the winter semester. Prof. Walther Straub, former head of the department and the leading pharmacologist in Munich, died in October 1944 at the age of 70. He was succeeded by his chief assistant, Dr. A. W. Forst. Professor Straub had been interested in the use of copper sulfate for phosphorus burns and nareotine as a substitute for codeine. It was stated that all this work had been published. In addition to teaching, one of the chief functions of the department was the standardization of digitalis and strophanthin preparations. This work was originally shared by Berlin, Leipzig and Munich as the result of a government order issued in 1928. Recently, owing to the overwork of Berlin and the bombing of Leipzig, this function fell entirely to Munich. Since the occupation, Munich has also ceased to perform this duty. The methods used were the frog method (animals kept at a constant temperature) and the Knafl-Lenz method of infusion into guinea pigs, with constant observation of the electrocardiographic changes. The firms for which standardization was performed included Merck, Ysaftabrik in Wernigerode and Hageda in Berlin. A small amount of private work had also been done for the Luitpoldwerk of Munich on the toxicity of styptics, one of which was an alcohol-ether extract of lung called Clauden (also used clinically by Prof. Dr. Wilhelm Stepp). Dr. Forst's private scientific interests revolved principally around the autonomic nervous system in relation to sleep, following largely on the ideas of Hess of Zurich. Dr. Forst stated that no work of military significance had been undertaken and that no new classes of synthetics had been studied. The department has been largely wrecked, all that is left being the lecture theater (slightly damaged) and a practical chemical laboratory at present without water or gas. The equipment for the testing of digitalis and strophanthin had been evacuated to Tutzing, about 25 miles southwest of Munich.

MEDICAL CLINIC

Prof. Dr. Wilhelm Stepp, the director of the medical clinic, stated that his interests have been mainly in the field of vitamin therapy. In addition to his discussion of the vitamin B complex and his advocacy of its use as a whole, he mentioned particularly the successful use of pantothenic acid in doses of 50 to 100 mg. daily by injection or by mouth in a limited number of cases of chronic bronchitis. He also suggested the study of its use in pneumonia. His supplies of pantothenic acid came from Hoffmann-LaRoche at Grenzach. He also mentioned the use of nicotinamide in chronic gastroenteritis and colitis. In 1944 Stepp lectured in Spain and Portugal on rational vitamin

therapy. He mentioned that the incidence of polyneuritis had greatly increased in the Munich area, particularly since 1939, especially among adults. Diphtheritic polyncuritis had also increased.

Stepp expressed an active interest in the employment of citrin in hemorrhagic diathesis and hemorrhagic retinitis and mentioned favorable clinical results. He had no knowledge of any methods for the standardization of citrin. In these conditions he often used vitamins C and K in conjunction with citrin. The citrin was supplied by I. G. Farbenindustrie. The gold compound Solganal is still being used in arthritis. He maintained that the blood substitute "Periston" was giving good results and stated that no liver damage had been observed. A few persons out of a group of 18 patients who had recently been sent to the clinic from Dachau were receiving Periston. He volunteered the information that he "had had no idea of the condition of affairs at the Dachau camp but had been under the impression that prisoners were employed on cultivation of medical plants, under good conditions of sunlight and air." Stepp referred to a stringent shortage of the purine alkaloids in Germany. He also mentioned the new (sixth) edition of *Die Vitamine* by Stepp, Kühnau and Schroeder, published in 1944 by Enke at Stuttgart. Stepp stated that Prof. Hans Fischer had recently committed suicide.

Anatomy Department—Division of Experimental Biology. Prof. Benno Romcis was not seen, as he had been evacuated from Munich to Dissen on the Ammersee. A copy of his book *Blutgefäss- und Lymphgefässapparat innersekretorischer Drüsen*, part 3, *Innersekretorische Drüse II Hypophyse* (Berlin, Julius Springer, 1940) was examined. It was well documented and illustrated but contained no matters of interest with regard to glandular preparations. Professor Bauer, who was the only staff member present, stated that the normal complement of students in the school of anatomy was approximately 600.

DERMATOLOGY DEPARTMENT

The head of the dermatology department, Dr. Julius Mayr, was absent at Starnberger See. His deputy, Dr. Hans Otto Münsterer, stated that he had been interested in vaccinal immunity in rabbits, but this work stopped during 1941 because of a lack of food for the animals. He reported that there had been relatively little occupational disease in the area, the main ones reported being cases of dermatitis due to light metals and hydrocarbon oil. Among outpatients a great increase in the incidence of pyoderma had been encountered. This condition was treated mainly with sulfonamides, particularly sulfathiazole. The sulfonamides have been in short supply and practically unobtainable recently. There has also been a scarcity of the arsphenamines, but the supply of bismuth preparations was adequate. In the treatment of syphilis practically no cases of jaundice were encountered, and on inquiry it was found that the syringes were boiled for each case. The incidence of syphilis in the war years was said to have increased more than tenfold. Dr. Münsterer stated that he had found a considerable incidence of venereal disease among foreigners in the area, except among the Russians. Scabies had increased. The preferred treatment was with "Mitigal." Benzyl benzoate was irritant and less effective. It does not appear that the civilian population has benefited directly from any advances in military medicine. It seems that drugs in short supply were reserved for the German army.

PSYCHIATRIC CLINIC

Prof. Oswald Bumke was visited in the Psychiatry Clinic in the Nürnberg Strasse. He gave a rapid summary of the work in his department. He himself had done little or no scientific research during the war. During this period, however, he had brought out the sixth edition of his *Lehrbuch der Geisteskrankheiten*, which is basically the same as the fifth edition. In the introduction to the fifth edition it was stated that the insulin-

metrazol-electric shock treatment would be introduced. In accordance with the new law the chapter on the state and the mentally ill was radically changed. Its relations to psychoanalysis were omitted. This was written in August 1941. Professor Bumke has also written a psychologic work, *Gedanken über die Seele* (Reflections on the Psyche) Julius Springer, of which there have been several printings, but a copy of this was unobtainable. He said it was psychologic and philosophical in content. Since the autumn of 1940 he had not been able to do any research because of his numerous clinical duties. Of his assistants and colleagues he mentioned one, Bannwarth, who had to go through the formality of joining the S. S. in order to become a dozent. Bannwarth had written a monograph entitled *Ueber entzündliche Erkrankungen des Nervensystems* (Inflammatory Diseases of the Nervous System). Among the subjects treated was inoculation polynuritis. Because of the description of nervous symptoms following some of these inoculations, publication was held up by the censor so that it might not be used for enemy propaganda. Bumke's comments were acid. This worker apparently specialized in roentgenography of the general nervous system, and encephalography. The apparatus which he used has been evacuated to Tegernsee. One of Bumke's former colleagues in the Kaiser Wilhelm Institut, Professor Beck, has completed a monograph on the cytoarchitectonics of the brain. This was published about 1941 by Springer. Professor Beck is now at Tutzing working in an observation field hospital. His interests seem mainly anatomic. Another of Bumke's assistants, Dr. Scheid, had been working on metabolism in insanity. Unfortunately this worker was shot by the S. S. about the time the Americans arrived in Tegernsee, to which he had been evacuated. Scheid had been implicated in the Bavarian freedom movement. Professor Bumke was of the opinion that biochemical studies of metabolism in insanity would be much more profitable than anatomic studies. An article, or perhaps a book, on *Psychogenische Störungen bei Kriegsteilnehmer* (Psychogenic Disturbances Among Servicemen) had been written by D. Ziehen, another of Professor Bumke's group. A copy of the manuscript had been sent to Berlin, but publication was forbidden, and Professor Bumke did not know whether there was another copy. However, Ziehen, who is at present at a hospital in Haar, may have an original typescript.

No work had been done with the electroencephalograph in Bumke's institute during the war, and apparently no new drug methods had been used, with the possible exception of the administration in schizophrenia of aminopyrine, which was scarce at the time of this visit.

State Bacteriologic Laboratory

The State Bacteriologic Laboratory, Dr. Willi Rimpau, director, in normal times performed the general bacteriologic work required by the area bounded by the Danube River, Lake Constance, Ulm and Berchtesgaden. It had four medical bacteriologists, one of them the director, some thirteen technical assistants, eight typists and nine clerks to carry on the work. The institute has been largely destroyed by bombing, however, and Dr. Rimpau is at present trying to start again on two floors of a former S. A. home, but this will require official sanction and funds. If he can get started he has about six months supply of material with which to work. He also mentioned the desirability of setting up some clinical chemical assistance for clinicians.

Bavarian Institute for Occupational Medicine

The Bavarian Institute for Occupational Medicine at Munich was completely gutted and its director, Dr. Franz Koelsch, could not be traced. The address left at the old institute was now a military headquarters.

BRAZIL

(From Our Regular Correspondent)

São Paulo, Sept. 25, 1945.

Treatment of Psychopathic Patients

The Serviço de Assistência a Psicopatas has undergone gratifying development during the administration of Dr. Fernando Costa in the state de São Paulo. Special attention has been given to the treatment and prevention of mental sickness. There are 8,755 patients in the hospitals of the Assistência, of whom 6,535 have entered during the administration of Dr. Fernando Costa. One of the first acts of the government was to enlarge the clinics of the Assistência, with the employment of twenty-two more doctors, some dentists and other assistants. A new hospital has been opened in Ribeirão Preto, with 400 patients and room for 1,000 beds. To attend to the patients in the rural districts Dr. Fernando Costa gave to the Assistência money to construct two outlying hospitals, one in the region served by the Central Railway and the other in the region served by the Sorocabana Railway.

Hospitals in Brazil

Hospital care in Brazil today can accommodate a large number of patients, although it has not attained complete development. In 1930 there were 607 hospitals in Brazil, which number had increased to 1,230 in 1943, located in different parts of the country. In 1930, with 42,729 beds, the number of patients cared for was 363,866. In the year 1940 653,263 patients were cared for. The number of hospital beds had increased to 109,338.

Personal

A ceremony in honor of Dr. Luis de Barros Lima, professor of surgery at the Medical School of Recife, state of Pernambuco, was held at the Santo Amaro Hospital, at which Dr. Monteiro de Morais, a professor at the school, described the twenty-five year medical career of Dr. Barros Lima, his numerous contributions to the medical literature and the prizes and medals awarded him for distinguished medical activities.

Dr. Julio Diez, Buenos Aires surgeon and professor at the university of that city, read three papers on gastroenterology at the auditorium of the Medical Division of the Bureau of Fisheries, Department of Agriculture, in Rio de Janeiro.

The University of São Paulo has released for publication a note about Dr. Edmundo Vasconcellos, professor of surgery, who is now at the Mayo Clinic in Rochester, Minn. Dr. Vasconcellos, who is accompanied by one of his assistants, Dr. Eugenio Mauro, has been invited by the U. S. State Department to visit, during three months, the principal universities of the United States to study the modern teaching of surgery.

Marriages

MARION RUDOLPH MODLEY JR., Florence, S. C., to Miss Elizabeth Louise Becker of Johnstown, Pa., August 25.

THOMAS WHITEHEAD MURRELL JR., Richmond, Va., to Miss Jane Nelson Goolrick of Fredericksburg, August 2.

GERALD J. NEMMERS, La Crosse, Wis., to Miss Rosemary Elfred in Forest City, Iowa, recently.

GLENN G. NEWMAN, Clinton, N. C., to First Lieut. Pearl Kaiser of Leesville, S. C., August 13.

LEO F. J. WILKING JR. to DR. VIRGINIA CENTER NICHOLS, both of New York, September 15.

JULIUS KARL NEILS, Portland, Ore., to Miss Gloria Mary Peck of St. Louis, August 10.

JOHN E. MILLER to Miss Emma Louise Schaefer, both of Quincy, Ill., in August.

HORACE H. LONG to Miss Nancy J. Nailor, both of Mechanicsburg, Pa., May 30.

LUETTE H. KUHLMAN to Mr. Jack DeVorss, both of Toledo, Ohio, in August.

Deaths

Thomas Benton Cooley * Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895; born in Ann Arbor, Mich., June 23, 1871; professor and head of the department of pediatrics from 1936 to 1941, when he became emeritus professor at the Wayne University College of Medicine; instructor at his alma mater from 1898 to 1900 and assistant professor of hygiene from 1903 to 1905; specialist certified by the American Board of Pediatrics, Inc.; member and past president of the American Pediatric Society, serving as a member of the governing council; charter member and past president of the American Academy of Pediatrics, serving also as executive secretary to its council for pediatric research; founder president of the Detroit Pediatric Society; past president of the Detroit Academy of Medicine; member of the American Institute of Nutrition, Society for Research in Child Development and the Society for Pediatric Research; major and assistant chief of the American Red Cross Children's Bureau in France during World War I; in 1924 awarded the Cross of Legion of Honor of France; for many years chief of the pediatric service and chairman of the staff of the Children's Hospital; on the consulting staff of the Harper, Woman's and Highland Park (Mich.) hospitals; died in the Eastern Maine General Hospital, Bangor, Maine, October 13, aged 74, of hypertensive heart disease. The clinical entity erythroblastic anemia is known as Cooley's disease.

Lee S. Huizenga, Shanghai, China; New York Homeopathic Medical College and Flower Hospital, New York, 1913; medical missionary in China for the Christian Reformed Church since 1920; served as superintendent of the mission hospital at Jukao and the new tuberculosis hospital in Shanghai after establishing a leprosarium there; at one time medical adviser to the American Mission to Lepers, carrying on leprosy investigations in the orient; in 1938 a delegate both from China and the United States to the International Leprosy Conference at Cairo, Egypt; at one time a minister in a church at Englewood, N. J., and a medical missionary to the Navajo Indians in New Mexico; died in a civilian internee camp in Chapei, China, July 16, aged 64, of peritoneal carcinoma.

George W. Mackenzie * Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1893; specialist certified by the American Board of Otolaryngology; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; past president of the Philadelphia Laryngological Society and the American Institute of Homeopathy; on the staffs of St. Luke's Hospital and the Children's Medical Center; in 1932 the University of Vienna bestowed on him a gold honor medal with a diploma of the university in recognition of his work in diseases of the eye, ear, nose and throat; died August 5, aged 73, of coronary thrombosis.

James Samuel Wolfstein, Cleveland; University of Michigan Medical School, Ann Arbor, 1922; member of the American Medical Association; member of the Academy of Medicine of Cleveland, serving as secretary and chairman of its section on obstetrics and gynecology; fellow of the American College of Surgeons; specialist certified by the American Board of Obstetrics and Gynecology; commissioned a major in the medical corps, Army of the United States, and served from September 1942 until he obtained his medical discharge in February 1944; for many years on the staff of the Mount Sinai Hospital, where he died July 27, aged 47, of carcinomatosis.

John Herbert Bliss * Brooklyn; Columbia University College of Physicians and Surgeons, New York, 1921; interned at the Methodist Hospital from June 1921 to October 1923, when he became a fellow in surgery and the following year a first assistant in radium therapy at the Mayo Foundation, Rochester, Minn.; member of the Brooklyn Surgical Society; fellow of the American College of Surgeons and the International College of Surgeons; attending surgeon, Brooklyn Cancer Institute; chief surgeon, second surgical division, Methodist Hospital Clinic, and associate surgeon at the Methodist Hospital, where he died October 1, aged 52.

Carl Benjamin Rosenkrans, East Stroudsburg, Pa.; Medico-Chirurgical College of Philadelphia, 1911; member of the American Medical Association; county medical director; state game commissioner and Republican county chairman; a captain in the medical corps with the 322d Infantry, serving

overseas during World War I; one of the founders of the General Hospital of Monroe County, where he served on the staff; physician and surgeon for the Lackawanna Railroad for many years; accidentally drowned, August 23, aged 57, when he was washed overboard from a fishing boat at Indian River Inlet, Rehoboth Beach, Del.

John Minor Blackford * Seattle; University of Virginia Department of Medicine, Charlottesville, 1910; specialist certified by the American Board of Internal Medicine; member of the North Pacific Society of Internal Medicine, Association of the Resident and Ex-Resident Physicians of the Mayo Clinic and the American Gastro-Enterological Association; fellow of the American College of Physicians; served on the staff of the Mayo Clinic, Rochester, Minn., from 1911 to 1917; one of the founders of the Mason Clinic and of the Virginia Mason Hospital, of which he was chief of staff and where he died September 12, aged 58.

George James Dennis * Chicago; Miami Medical College, Cincinnati, 1887; Northwestern University Medical School, Chicago, 1898; specialist certified by the American Board of Otolaryngology; emeritus member of the Illinois State Medical Society; member of the American Academy of Ophthalmology and Otolaryngology; at one time associate in laryngology at the Northwestern University Medical School; served on the staffs of the Wesley Memorial and Grant hospitals; died in the Passavant Memorial Hospital May 21, aged 79, of duodenal ulcer, generalized arteriosclerosis and myocardial infarction.

William Kieper Kistler, Philadelphia; Hahnemann Medical College and Hospital of Philadelphia, 1928; member of the American Medical Association; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; served on the faculties of the Graduate School of Medicine of the University of Pennsylvania and his alma mater; on the staffs of the Delaware County Hospital, Drexel Hill, and the Hahnemann, Mount Sinai and Broad Street hospitals; visiting assistant surgeon, Abington (Pa.) Memorial Hospital; died July 27, aged 46, of heat exhaustion.

Craig Barrow, Savannah, Ga.; University of Maryland School of Medicine, Baltimore, 1900; member of the American Medical Association; for many years chief surgeon of the Central of Georgia Railway and its hospital; formerly medical superintendent, vice president and president of the Georgia Infirmary; served in the medical corps of the U. S. Army during World War I; at one time alderman; served as governor and lieutenant governor of the Society of Colonial Wars in the state of Georgia; died in a local hospital August 31, aged 69, of cerebral hemorrhage.

George Hursh Ensminger, Chicago; Medico-Chirurgical College of Philadelphia, 1905; clinical instructor in otorhinolaryngology at the Loyola University School of Medicine; served as health officer of Glen Ellyn and as medical consultant for several railroad companies; junior attending ophthalmologist and rhino-otolaryngologist at the Mercy Hospital, where he had been chief of the eye clinic from 1918 to 1922; assistant to the chief aurist at the Illinois Central Hospital, where he died August 23, aged 67, of hypertensive heart disease and glomerulonephritis.

Walter Baumgarten * St. Louis; Washington University School of Medicine, St. Louis, 1896; served on the faculty of his alma mater; formerly secretary of the Missouri State Medical Association and editor of its journal; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; formerly associated with the U. S. Public Health Service; on the staffs of the Barnes, St. Luke's and Jewish hospitals; burned to death, August 23, aged 72, when his summer home near Fish Creek, Wis., caught fire.

William Douglas Anderson, Tarpon Springs, Fla.; University of Georgia Medical Department, Augusta, 1924; member of the American Medical Association; on the staff of the Morton F. Plant Hospital in Clearwater; died in Wilmington, Del., August 15, aged 51, of bleeding duodenal ulcer.

Richard Wortman Baker, Pasadena, Calif.; Beaumont Hospital Medical College, St. Louis, 1893; member of the American Medical Association; died June 7, aged 81, of arteriosclerosis.

John Joseph Bartley, Lawrence, Mass.; Harvard Medical School, Boston, 1901; member of the American Medical Association; formerly city physician; supervisor of school physicians for the city of Lawrence; died June 16, aged 73, of cerebral hemorrhage.

James William Baxter Sr. ☉ New Albany, Ind.; Kentucky School of Medicine, Louisville, 1903; past president of the Floyd County Medical Society; served in the medical corps of the U. S. Army during World War I; on the staff of St. Edward's Hospital; died August 28, aged 72, of cerebral hemorrhage and encephalitis.

Alvin Benton Caldwell, Forrest City, Ark.; Memphis (Tenn.) Hospital Medical College, 1911; member of the American Medical Association; county health officer; died in the Baptist Memorial Hospital, Memphis, Tenn., July 27, aged 66, of coronary embolism.

Georgina Helme Carruthers, Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1900; member of the American Medical Association; died August 23, aged 84, of senility.

Dana Lawrence Cavendish, Fayetteville, W. Va.; Medical College of Virginia, Richmond, 1927; served during World War I; a captain in the medical corps, Army of the United States, from May to August 1942, when he was released; died August 3, aged 47, of heart disease.

Joel Toy Curry, Macon, Ga.; Columbian University Medical Department, Washington, D. C., 1897; formerly chief medical officer, retirement division, U. S. Civil Service Commission in Washington, D. C.; died in Lakewood June 30, aged 73, of coronary occlusion.

William David Davis, East Canton, Ohio; Tennessee Medical College, Knoxville, 1823; member of the American Medical Association; for many years president of the board of education; formerly on the staff of the Antman Hospital, Canton; died August 22, aged 77, of arteriosclerosis.

Louis Alexander Denis, Red Bank, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; died August 2, aged 72, of coronary occlusion.

George Stephen de Renyi, Philadelphia; Magyar Királyi Pázmány Petrus Tudományegyetem Orvosi Fakultása, Budapest, Hungary, 1916; associate professor of anatomy at the University of Pennsylvania School of Medicine and the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; member of the American Association of Anatomists; died in the University Hospital August 24, aged 53, of cirrhosis of the liver.

John M. Fawcett, Coral Gables, Fla.; Pulte Medical College, Homeopathic, Cincinnati, 1889; died in the Ohio Valley General Hospital, Wheeling, W. Va., August 5, aged 81, of carcinoma of the gallbladder.

George Edwards Fay ☉ Detroit; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1931; at one time affiliated with the Standard Life and Accident Insurance Company; served during World War I; died in Grosse Pointe August 23, aged 70, of heart disease.

John McKelvey Foster, Birmingham, Ala.; Memphis (Tenn.) Hospital Medical College, 1910; member of the American Medical Association; physician for the juvenile court; died in the Jefferson Hospital August 9, aged 65, of coronary occlusion.

Bernard S. Gostin ☉ Macon, Ga.; College of Physicians and Surgeons, Baltimore, 1903; on the staff of the Macon Hospital; died August 28, aged 65, of coronary occlusion.

Michael Anthony Griffin ☉ Chicago; Rush Medical College, Chicago, 1896; served on the staffs of the Columbus, St. Joseph and American hospitals; died August 23, aged 75, of chronic myocarditis.

John M. Higgins, Athens, Ohio; Pulte Medical College, Homeopathic, Cincinnati, 1893; health commissioner of Athens for many years; on the staff of the Sheltering Arms Hospital; died June 30, aged 83, of heart disease.

Francis Marion Hiller, Carterville, Ill.; St. Louis College of Physicians and Surgeons, 1909; member of the American Medical Association; on the staff of the Holden Hospital, Carbondale, where he died August 31, aged 66, of coronary occlusion.

John Henry Hovenden ☉ Laurens, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; died August 28, aged 71, of coronary thrombosis.

Nathan Louis Jacobson, Lynn, Mass.; Maryland Medical College, Baltimore, 1910; member of the American Medical Association; on the staffs of the Lynn and Union hospitals; died in the Beth Israel Hospital, Boston, July 13, aged 62, of pulmonary embolism.

William Kilburn Jaques, Chicago; Chicago Medical College, 1887; died August 6, aged 86, of cerebral hemorrhage.

Thomas Gotthart Jenny ☉ Pittsburgh; Western Pennsylvania Medical College, Pittsburgh, 1907; died in Miami Beach, Fla., August 31, aged 59, of coronary heart disease and nephritis.

Alice Elizabeth Johnson ☉ Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1905; member of the American Psychiatric Association; for many years clinical professor of psychiatry at her alma mater; formerly a druggist; at one time resident physician at the Pennsylvania Hospital, Department for Mental and Nervous Diseases; since 1920 psychiatrist at the Municipal Court; died in the Woman's Hospital July 19, aged 72, of cerebral thrombosis.

Forrest A. Kelley ☉ Winfield, Kan.; John A. Creighton Medical College, Omaha, 1906; for many years county health officer; on the staffs of the William Newton Memorial and St. Mary's hospitals; died July 14, aged 67, of coronary thrombosis.

Robert Oliver Kevin, Philadelphia; Jefferson Medical College of Philadelphia, 1882; for many years on the staff of the Jefferson Hospital; died July 30, aged 90, of acute dilatation of heart and arteriosclerosis.

George L. Lanus, Beaumont, Texas (licensed in Texas under the Act of 1907); died in St. Theresa Hospital July 8, aged 78, of diabetes mellitus and acute nephritis.

Gaspar Emmanuel Leontine, Boston; College of Physicians and Surgeons, Boston, 1917; died June 10, aged 72, of coronary thrombosis.

Brooklyn Boyer Levengood, Bellwood, Pa.; Jefferson Medical College of Philadelphia, 1889; served overseas during World War I; in 1940 was presented with a fifty year testimonial certificate at a meeting of the Sixth Council District of the Medical Society of the State of Pennsylvania; on the staffs of the Mercy Hospital, Altoona, and the Nason Hospital, Roaring Springs; died July 6, aged 77, of cerebral hemorrhage.

Aaron Yancy Linville, Winston-Salem, N. C.; University of the City of New York Medical Department, New York, 1889; member of the American Medical Association; honorary member of the Medical Society of the State of North Carolina; died July 7, aged 82, of heart disease.

William Alex MacLeod ☉ New York; University of the City of New York Medical Department, 1896; died in the Yarmouth Hospital, Yarmouth, N. S., August 5, aged 76.

Joseph Elmer Magee ☉ Carnegie, Pa.; University of Pittsburgh School of Medicine, 1914; formerly Burgess of the borough of Carnegie; died August 2, aged 54, of brain tumor.

Percy Edwin Dunlop Malcolm ☉ New York; Bellevue Hospital Medical College, New York, 1893; an Affiliate Fellow of the American Medical Association; member of the American Laryngological, Rhinological and Otolological Society; fellow of the New York Academy of Medicine; specialist certified by the American Board of Otolaryngology; on the staffs of the Manhattan Eye, Ear and Throat and the Metropolitan hospitals; died in Mount Tremblant Lodge, Que., Canada, August 12, aged 75.

Benjamin Lake Noyes ☉ Stonington, Maine; Medical School of Maine, Portland, 1895; died in the Eastern Maine General Hospital, Bangor, October 16, aged 75, of pneumonia.

Charles E. O'Bryan, Mortons Gap, Ky.; University of Tennessee Medical Department, Nashville, 1899; member of the American Medical Association; died August 8, aged 77, of heart disease.

William John St. Clair O'Callaghan, Nashville, Tenn.; University of Tennessee Medical Department, Nashville, 1904; served as postmaster and postal official for many years; past president and for many years member of the board of directors of the Y. M. C. A.; died July 14, aged 77, of coronary thrombosis.

Sarah Ellen Palmer, Boston; Woman's Medical College of Pennsylvania, Philadelphia, 1880; member of the American Medical Association; fellow of the New England Hospital for Women and Children; died August 23, aged 89, of myocardial failure and paralysis agitans.

Ernst J. Panetti, Milwaukee; Milwaukee Medical College, 1901; member of the American Medical Association; died August 24, aged 79, of coronary thrombosis and arteriosclerosis.

William H. Parsons, Newcastle, Maine; University of Vermont College of Medicine, Burlington, 1885; member of the American Medical Association; honorary member of the Maine Medical Association; trustee of the Miles Memorial Hospital in Damariscotta; died June 8, aged 84, of angina pectoris.

Alice Maria Patterson, Marblehead, Mass.; Boston University School of Medicine, 1893; Tufts College Medical School, Boston, 1904; member of the American Medical Association and the New England Society of Psychiatry; served as senior physician for the Wrentham State School in Wrentham; died in Danvers June 20, aged 75, of carcinoma of the pancreas.

Paul Jacob Pauliny, Tucson, Ariz.; Deutsche Universität Medizinische Fakultät, Prague, Czechoslovakia, 1927; on the staff of the San Xavier Indian Sanatorium, where he died July 22, aged 43, of hypertension, nephritis and congestive heart disease.

Richard Kirtley Pemberton & McAlester, Okla.; Missouri Medical College, St. Louis, 1895; served two terms as mayor of the city of McAlester; active member of the staffs of St. Mary's and Albert Pike hospitals; died September 24, aged 74, of coronary occlusion.

James McIlvaine Phillips, Galloway, Ohio; University of Pennsylvania Department of Medicine, Philadelphia, 1898; at one time professor of pathology at the Ohio State University College of Medicine; died in the Grant Hospital, Columbus, July 28, aged 71, of shock following a prostatectomy.

Chester Arthur Poe & St. Louis; St. Louis College of Physicians and Surgeons, 1914; at one time coroner of Cape Girardeau County; on the staff of the Missouri Baptist Hospital, where he died August 3, aged 58, of cerebral hemorrhage.

Philip Henry Quick, Olivet, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1895; past president of the Eaton County Medical Society; member of the American Medical Association; past president of the local school board; formerly bank president; died in Battle Creek August 11, aged 78, of cerebral hemorrhage.

Edwin V. Ross, Rochester, N. Y.; Homeopathic Hospital College, Cleveland, 1890; at one time associated with the city health department; died August 6, aged 78, of carcinoma of the face.

Edward Sturgis Rutledge, Jolmstown, Ohio; Ohio Medical University, Columbus, 1897; died July 18, aged 82, of cerebral hemorrhage.

Dorsy McNeelas Ryan, Charleston, W. Va.; Medical College of Virginia, Richmond, 1906; member of the American Medical Association; served in the medical corps of the U. S. Army during World War I; died September 19, aged 67, of acute myocardial insufficiency.

Guy W. Seaton & Indianapolis; Medical College of Indiana, Indianapolis, 1898; associate in otolaryngology, Indiana University School of Medicine; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Otolaryngology; died in the Methodist Hospital August 12, aged 61, of coronary occlusion.

Albert Newton Seidel, Reading, Pa.; Baltimore Medical College, 1891; died in St. Joseph Hospital June 28, aged 78, of coronary thrombosis and influenzal pneumonia.

Daniel Walter Sheek, Greenwood, Ind.; Medical College of Indiana, Indianapolis, 1903; member of the board of health; served as coroner; died in St. Vincent's Hospital, Indianapolis, August 28, aged 73, of coronary occlusion.

Bradford Wyckoff Sherwood, Syracuse, N. Y.; Hahnemann Medical College and Hospital of Philadelphia, 1890; died August 29, aged 86, of senility.

John Shirk Simons & Marietta, Pa.; Jefferson Medical College of Philadelphia, 1923; served on the staff of St. Joseph's Hospital in Lancaster; died July 20, aged 63, of coronary occlusion.

Benjamin L. Smith, Forsyth, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1906; member of the American Medical Association; died in the Mercy Hospital, Macon, July 7, aged 62, of angina pectoris.

John Morrison Sokol & Spencer, Iowa; Rush Medical College, Chicago, 1902; for many years county coroner; died July 22, aged 69, of coronary thrombosis.

Thomas Alvin Son, Bonne Terre, Mo.; American Medical College, St. Louis, 1899; for many years a member of the state board of health; died in Kirkwood July 11, aged 88, of nephritis and fracture of the left hip received in a fall.

John Murdock Stewart, Marion Center, Pa.; University of Pittsburgh School of Medicine, 1908; served during World War I; died in the Veterans Administration Facility, Aspinwall, June 29, aged 67, of coronary heart disease.

Albert Edward Snow, St. Louis; American Medical College, St. Louis, 1893; died August 13, aged 75, of arteriosclerosis.

Charles De Witt Voorhees, Clearwater, Fla.; University of the City of New York Medical Department, New York, 1889; member of the American Medical Association and the Medical Society of the State of Pennsylvania; died July 22, aged 88, of congestive heart disease.

Lucy Nye White, Freetown, Mass.; Illinois Medical College, Chicago, 1902; died June 1, aged 84, of cerebral hemorrhage.

William L. Wilson, Scipio, Ind.; Beach Medical College, Indianapolis, 1886; member of the American Medical Association; died August 28, aged 85, of carcinoma of the prostate.

Edward Archer Wight, Bolsters Mills, Maine; Medical School of Maine, Portland, 1889; died in Wakefield July 23, aged 81, of heart disease.

PUBLIC HEALTH SERVICE

Robert Olesen & Medical Director, U. S. Public Health Service, Staten Island, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1905; born in New Ulm, Minn., May 22, 1883; served an eighteen month internship in Providence Hospital, Washington, D. C.; on April 1, 1908 commissioned an assistant surgeon in the regular public health service; from 1909 to 1913 served as quarantine and immigration officer in Manila, Mariveles and Iloila, serving in the last as district health officer in cooperation with the Insular Board of Health; on completion of a course at the Hygiene Laboratory, Washington, D. C., in 1913 assigned to study industrial health conditions for the U. S. Commission on Industrial Regulations in Minnesota, Michigan, Illinois and Ohio; during World War I conducted industrial surveys in New York, New Jersey, Pennsylvania, Illinois and Wisconsin for the newly created office of industrial hygiene and sanitation; served as medical director of extracantonment areas in Kentucky and Alabama; credited with organizing the bureau of communicable disease control, Wisconsin State Board of Health, in 1919 and the North Dakota State Department of Health in 1922; from 1923 to 1929, while in charge of the Office of Goiter Studies, with headquarters in Cincinnati, organized the large scale goiter surveys in various parts of the country; in 1930 assigned to the American embassy in Berlin, where he was in charge of physical and mental examinations of emigrants to the United States; returned to the United States in 1934 and assigned to the Farm Security Administration, for whose clients he developed a public health and medical program; in April 1936 assigned as assistant surgeon general in charge of the division of sanitary reports and statistics, U. S. Public Health Service; in 1939 assigned to the Foreign Quarantine Station at Rosebank; became a passed assistant surgeon in the U. S. Public Health Service in July 1912, surgeon in June 1920, senior surgeon in July 1930 and medical director in March 1934; died at his home in the quarantine station, Rosebank, August 15, aged 62, of cerebral hemorrhage.

Bruno Solby & Surgeon, U. S. Public Health Service (R), Federal Security Agency, Washington, D. C.; Medizinische Fakultät der Universität Wien, Vienna, Austria, 1932; member of the Society of American Bacteriologists, American Sociological Society and the Medical Society of the State of New York; associate member of the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology, Inc.; took postgraduate work in neuropathology, neurology and psychiatry at the New York Post-Graduate Hospital, where he had been assistant neurologist and psychiatrist; a captain in the medical corps, Army of the United States, from August 1942 to October 1943, when he was honorably discharged; joined the public health service in November 1943; detailed to the U. S. Public Health Service Dispensary, Washington, where he died September 8, aged 41, of cerebral hemorrhage.

Henry S. Wolanczyk, Assistant Surgeon, U. S. Public Health Service Reserve, Buffalo; University of Buffalo School of Medicine, 1940; diplomate of the National Board of Medical Examiners; interned at the U. S. Marine Hospital in San Francisco; joined the public health service reserve on July 1, 1941; served as public health officer for the Laclede County Health Department in Lebanon, Mo.; assigned to Coast Guard aboard the U. S. S. *Harveston* Oct. 1, 1943; died in the U. S. Marine Hospital, Portsmouth, Va., Dec. 23, 1943, aged 28.

Bureau of Investigation

SEKOV DANGEROUS TO HEALTH

Federal Court Forbids Further Interstate Sale of "Reducer"

"Home treatments" for obesity frequently contain thyroid, with all its dangerous side effects. Disastrous results from self dosing with these preparations are common. Certain such "cures" have persisted in the market for years in spite of the government's efforts to protect the public by checking their sale. The perennial "Marinola" is a conspicuous example.

Another such nostrum—"Sekov"—has thrived for at least ten years, although actions against its promoters have been initiated by two federal agencies. Sekov is the reverse spelling for "Vokes," the name of its backers, Edwin H. and Hazel R. Vokes of Hollywood, Calif., whose latest trade styles appear to be "Sekov Studios" and "Sekov Corporation." An investigation made a few years ago indicated that Hazel Vokes got her start in the weight-reducing business by working for Gertrude Nova, Inc., of Hollywood, apparently a trade style for a woman who was sometimes known variously as Gertrude Nova and Gertrude Tenderich, and who was once in a similar

WHY BE FAT?

USE SEKOV!

**A Safe Reducing Preparation
FOR MEN AND WOMEN**

Sekov, a physician's prescription registered in Washington, D. C., has been used with remarkable success for reducing overweight by persons of all ages—from 7 year old children to persons 83 years of age. No rigid diets, no exercise, no loss of time.

Send for FREE booklet today!

Advertisement of a Sekov agent

business in Denver called the Avon Laboratories (note that "Avon" is the reverse spelling of "Nova"). Apparently this person sold out her Denver concern and established a similar one in Hollywood, reportedly at the same address as that later used by the Vokes-Sekov outfit. Hazel Vokes is said to have bought the Nova business in 1935. Presumably the formula of the Nova nostrum—long alleged to contain thyroid—was included in the reported sale of her business to Hazel Vokes.

In August 1936 the Los Angeles Health Department reported that when it was investigating Sekov an agent supplied two "formulas" for it, as follows:

- | | | |
|-------|--------------------------------|----------------------|
| No 1. | Thyroid 1½ gr. | |
| | Big pill whole Pit 1 gr. | |
| | Big pill whole Ova. 3 gr | |
| | R ½ is ½ of No 1. | Digitalis ½ gr |
| No 2. | Rhubarb root 2 gr. | Cascara Sagrada 1 gr |
| | Aloni ½ gr. | Asafetida ½ gr |
| | Oleoresin ginger ½ gr | |
| | T. ½ size Digitalis ½ gr | Thyroid 2 gr |
| | P. ½ size Whole Pit. 2 gr | Thyroid 1 gr |
| | O. ½ size 2 gr. Ova whole 1 gr | Whole Pit |

The presence of thyroid in these nostrums was later confirmed by chemists of the Food and Drug Administration. According to their report, each carton of the nostrum contained two types of capsules, "No 1" and "No 2." The No 1, they said, consisted of glandular material, including thyroid in amounts ranging from 1.84 to 1.95 grains per capsule, the No. 2 rhubarb root, cascara sagrada bark, aloni and asafetida, and the "Formula P" approximately 172 grains of thyroid per capsule.

The first government agency to take action against the Vokes persons was the Federal Trade Commission, which, on Sept. 26,

1940 ordered them to discontinue any of their advertisements which did not warn that the use of Sekov under the conditions prescribed in the advertising, or those customary or usual, might result in serious or even irreparable injury to health. The Commission's findings included the charge that even when Sekov might produce a reduction in weight by accelerating the rate of metabolism it might seriously weaken the body and its organs, including the heart, by means of the thyroid present. The details of this case were given in *THE JOURNAL*, Aug 9, 1941, page 472.

In March 1945 the Food and Drug Administration published the results of two actions that it had brought against the Sekov outfit following the seizure of interstate shipments of Sekov preparations. The seizures were based on the charge that the articles were misbranded under the Food, Drug and Cosmetic Act in that the labeling was false and misleading, that the nostrums would be dangerous to health when taken in the dosage or with the frequency or duration recommended on the labels, and that the latter failed to give adequate directions for use and such warnings as are necessary in the case of thyroid and laxative preparations. One product, the "Formula P," was also declared to be adulterated in that each tablet contained more than the 1 grain of thyroid represented. These findings were confirmed by a district federal court in California despite the protests of the Sekov promoters, and the charge of misbranding was sustained under Notice of Judgement No. 1002, issued in March 1945.

In this connection, Notice of Judgment No. 1001 reported that, in view of the danger attending the use of the Sekov nostrums, the court issued an injunction forbidding the Vokeses thereafter to ship any of their products known as "Sekov," "Sekov Reducer," "Sekov Reducer for Men" and "Sekov Formulas P, R and T" in interstate commerce, which action means that they cannot be shipped out of California because they are potentially dangerous to health.

Thus the public outside of California is to be protected from the risk involved in taking Sekov. Whether the California officials will be willing to "harm home industry" by restricting the sale of Sekov in its own state, or simply follow the "caveat emptor" policy, remains to be seen.

SOME MISCELLANEOUS MEDICAL FRAUDS

A Variety of Schemes Debarred from the Mails

Fraud orders issued by the Post Office Department have frequently been the subject of extensive articles by the Bureau of Investigation in these pages of *THE JOURNAL*. Following is a brief abstract of one such fraud order:

Perma Company and Twil-Gro Company.—These were trade styles used by one Ollie Altman of Brooklyn in selling through the mails a product known as "Perma Youthskin" or "Perma Smoothskin." This, he represented, would remove wrinkles and crows' feet, benefit scrawny necks, restore the texture of the skin and the appearance and biggy eyelids, restore the former youthful condition, regardless of the age of the user to their former youthful condition. After the Post Office Department had investigated the whole business, it notified Altman to appear at a hearing in Washington and answer to a charge of using the mails to defraud. He did not appear, but sent counsel. A government chemist testified that his analysis of Perma Youthskin disclosed 35 per cent of paraffin and spermaceti, about 29 per cent of lanolin, nearly 20 per cent of water, more than 10 per cent of beeswax, 5 per cent of turtle oil, less than 1 per cent of borax, and a trace of perfume. A Senior Medical Officer of the Food and Drug Administration also testified for the government, showing that wrinkles are a natural accompaniment of age, but may result from some other causes, such as sudden and considerable loss of weight, under nonnourishment, improper functioning of certain endocrine glands, and constant exposure to the glare of the sun. He discussed the structure of the skin and its tissues, and showed the futility of attempting to correct deep wrinkles by a combination of turtle oil and lanolin, which ingredients the promoters of Perma Youthskin particularly emphasized. He testified, further, that turtle oil has no more beneficial effects on the skin than any other animal oil, and that the preparation in question would benefit the skin no more than any other grease applied to it with massage. He pointed out that the product did not supply or build up the missing tissues, though it might cause some of the fine lines in the face to be temporarily less apparent. Even the unnamed physician who testified for the defendant admitted the foregoing statements about turtle oil and agreed with the government testimony that biggy eyelids resulting from systemic diseases could be removed only by treatment and cure of such diseases. On May 4, 1944, a fraud order was issued to delar from the mails the business operating under the names Perma Company and Twil-Gro Company, and their officers and agents.

Correspondence

DEATH FROM AIR EMBOLISM FOLLOWING INSUFFLATION DURING PREGNANCY

To the Editor:—In the article by Dr. Herbert S. Breyfogle entitled "Death from Air Embolism Following Insufflation During Pregnancy" (*THE JOURNAL*, September 29, p. 342) the statement is made that "the following death from air embolism resulting from insufflation during pregnancy is therefore the fourth from this means to be reported, and the first to be recorded in the medical literature of this country."

My interest was aroused, since I had reported two deaths from air embolism due to the use of vaginal powder insufflators (one during pregnancy) in the May 1945 issue of the *American Journal of Surgery*. This was approximately four months before the publication of Breyfogle's paper. Therefore, although I hate to enter into discussion about such small issues, it seemed that there might be some question as to the accuracy of the statement quoted. This author, evidently after reading my publication in May and apparently without investigation, added the following reference to his article:

14. Since this article was submitted for publication an additional death from air embolism following insufflation during pregnancy has been reported (Martland, H. S.: Air Embolism: Fatal Air Embolism Due to Powder Insufflators Used in Gynecologic Treatments, *Am. J. Surg.* 130: 164 [May] 1945).

Investigation at the office of *THE JOURNAL* indicates that Breyfogle's article "was submitted to *THE JOURNAL* under date of Feb. 23, 1945," whereas the editor of the *American Journal of Surgery* informs me that my article was submitted Jan. 29, 1945. Therefore if we are to follow the established custom that "priority is usually calculated from the date when the article is received in the office of publication," the statement by Breyfogle that his case was "the first to be recorded in the medical literature of this country" is quite inaccurate.

However, except "to keep the record straight," priority is apparently of little significance in the report of this type of case. For it is undoubtedly true that similar catastrophes have occurred prior to the cases reported, but because of medicolegal reasons (civil suits, criminal liability and the like) have remained unreported. This is strongly supported by the experience of medical examiners in the Metropolitan Area of New York, who not infrequently investigate cases of death due to air embolism.

These deaths usually follow criminal abortions, especially by the syringe method, and wounds of and operations on the neck, upper thorax or head which involve the dural sinuses. Less frequently are encountered deaths following diagnostic and therapeutic uterine injections, transuterine pneumoperitoneum, lavage of the nasal sinuses, especially the antrum of Highmore, aerograms of the bladder, placenta previa and air injection in the region of the adrenal glands for roentgenographic visualization (Martland, H. S.: Air Embolism, with Special Reference to Its Surgical Importance, *Am. J. Surg.* 68:281 [June] 1945).

HARRISON S. MARTLAND, M.D., Newark, N. J.
Chief Medical Examiner of Essex County.

To the Editor:—Dr. Breyfogle's report of a death from air embolism following insufflation during pregnancy (*THE JOURNAL*, September 29, p. 342) interested me deeply. Contrary to Dr. Breyfogle's mention of the first reference in medical literature to insufflation into the vagina in 1936, I have to say that the dry treatment of discharge of different kinds by insufflation was used in Europe much earlier. I myself published about a hundred cases dealing with this in December 1912 in the *Therapie der Gegenwart*, stimulated by the publica-

tion of Nassauer and Abraham some years prior. Fortunately we had not had any deaths by insufflation because we did not use this method in pregnancy, as far as I recall.

While the aforementioned authors used the Nassauer insufflator, I preferred not to do this. I noticed in beginning of my dry treatments the defects and insufficiencies of this instrument, which are (1) frequent obstruction and therefore blowing of a great amount of air into the vagina by forceful manipulation of the physician, (2) requirement of much time to bring into the vagina the intended quantity of the powder and (3) the time needed for the changing and sterilization of the nozzle of the insufflator, which is almost impossible in a big practice or a crowded clinic.

Therefore I changed my technic in 1912. I took a piece of paper, which I folded at both sides, placing the powder (2 to 3 Gm.) in the center and inserted the speculum into the vagina. I put the powder on the speculum and applied it by means of a forceps with cotton everywhere I wanted it (to the portio and vaginal walls), which procedure was accomplished by movements of the speculum. Instead of a piece of paper I now use the glass tube in which the powder is supplied. The success of this treatment and technic was excellent and I imagine also more effective than insufflation because more powder can be brought in. Besides the dangers reported by Dr. Breyfogle can be avoided through this. There is no positive air pressure as by insufflation.

The advice given by the author to abandon insufflation in cases of pregnancy and multiparas should be considered. With the explanation of my technic of dry treatment of discharge regardless of cause, I want to make it clear that this administration of the powder avoids the dangers of the insufflator, even in cases of pregnancy and multiparas.

HEDWIG PRAGER, M.D., New York.

FOOD POISONING BY SALMONELLA MONTEVIDEO

To the Editor:—In *THE JOURNAL*, September 1, an outbreak of food poisoning due to *Salmonella montevideo* in an army general hospital is reported. That outbreak possibly was not as local as the authors believe. During the night of April 16-17, 1944 there was a similar outbreak in another hospital in southern England. As the outbreak took place a few days before that hospital started to admit patients, all cases were personnel from that hospital, approximately 250 out of 400. The cases came from both hospital messes (officers' and enlisted men's). The symptoms (abdominal cramps, watery diarrhea, nausea, high fever) were the same as described in the April 11-12 outbreak. Several patients had cough and expectoration, one with definite pneumonic signs on physical examination. The hospital's x-ray equipment had not been set up yet.

Our experience with sulfaguandine (3 Gm. every four hours) was apparently satisfactory. The 30 patients (two wards) treated with that drug in adequate doses improved faster and were returned to duty within three and four days after the onset of symptoms. Others required from four to fourteen days of hospitalization, and the patient with frank pneumonia recovered in approximately four weeks under sulfadiazine therapy.

The organism in the stools that had been sent to the First Medical Laboratory was identified as *Salmonella montevideo*.

Medical officers with field units in the neighborhood told me of similar outbreaks during the same week.

Although it is possible that these outbreaks of *Salmonella montevideo* food poisoning were independent of one another and just happened during the same week, one has to consider the possibility of their having a common source rather than cook carriers.

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Graduate of Middlesex University Not Entitled to Licensure in New Jersey.—Rothseid, a "graduate of Middlesex University School of Medicine of Massachusetts," after examination was licensed to practice medicine and surgery in Massachusetts. Thereafter he served as a resident physician in the Lawrence General Hospital, Lawrence, Mass. Subsequently he applied to the state board of medical examiners of New Jersey in the alternative either for a license by reciprocity on the basis of his Massachusetts license or to be admitted to an examination for a license. The applicable sections of the New Jersey medical practice act require an applicant for a license to practice in New Jersey to have received a diploma from a professional school which in the opinion of the board "was in good standing at the time of the issuance of the diploma." Since Middlesex University, in the opinion of the board, was not in good standing either at that time or at the time of the issuance of the diploma to Rothseid, Rothseid's application was denied by the board. Rothseid then sought a writ of mandamus either to compel the board to license him by virtue of his Massachusetts license or to admit him to examination for such a license, and the matter came before the supreme court of New Jersey.

The question to be determined here, said the supreme court, is whether the board of medical examiners is justified in classifying Middlesex University School of Medicine as an institution which was not in good standing. The board bases its conclusion in the grading and standing of medical schools on the standard adopted by the "Committee of Education" (presumably the Council on Medical Education and Hospitals) of the American Medical Association and makes public the names of the schools which it approves. Rothseid argued that the action of the board in accepting the grading of medical schools by the American Medical Association "is without using its own judgment or discretion but constitutes an unlawful delegation of its duty and power." We do not agree with Rothseid's contention, continued the court. We think the board of medical examiners is entirely within its discretion to adopt the standard and grading of an organization of which it has knowledge and confidence. We think the board acted within its sound discretion within the meaning of the medical practice act and was not actuated by arbitrariness or capriciousness. Compare *Salowitz v. Michigan State Board*, 285 Mich. 214, 280 N. W. 737; *Rosenthal v. State Bar Examining Committee*, 116 Conn. 409, 165 A. 211, 87 A. L. R. 991.

The court accordingly concluded that Rothseid had not shown any violation of his rights which entitled him to a writ of mandamus and therefore denied his application for such a writ. —*Rothseid v. State Board of Medical Examiners*, 38 N. J. (2d) 444 (N. J., 1944).

Hospitals: Duty to Safeguard Delirious Patient from Self Injury.—For a number of years the plaintiff had been addicted to the excessive use of liquor and on Jan. 5, 1943 voluntarily entered a sanatorium conducted by the defendant corporation "for the cure of chronic alcoholics." She was assigned a room on the second floor of the institution. When she entered the sanatorium she was highly nervous and later at times was "delusional." She did not recognize a relative who visited her. She labored under the impression that she was in an insane asylum and was discovered scrubbing the floor of her room thinking it was her kitchen floor at home. Apparently, she was subject to restraint of no nature at the sanatorium. About two days after her admittance she was found seriously injured lying on the cement pavement below the window of her room from which she had either jumped or fallen. Subsequently she instituted suit against the defendant for damages, charging that the defendant was negligent in failing to guard and restrain her and in failing properly to bar her window to prevent her plunging through the window to the ground below. At the conclusion of the plaintiff's evidence the trial

court directed a verdict in favor of the defendant and entered judgment thereon. The plaintiff then appealed to the district court of appeal, second district, division 2, California.

The defendant sanatorium, said the appellate court, was under the obligation to use reasonable care in providing for and in guarding the safety of its patients, the obligation to use the care and take the precaution to prevent danger which a reasonable man would take under the circumstances shown to exist. The circumstances to be considered here included the patient's mental and physical condition and what she was likely to do because of that condition; but the defendant's obligation was subject to the rule that it was not required to use greater care than a reasonable person would exercise under the circumstances. The defendant was not required to take measures to avert injury to its patients which circumstances did not indicate to be reasonably necessary. Specifically, the defendant was not required to restrain its patient or bar its windows unless facts were brought to its attention showing that it was reasonably probable that the patient would do injury to herself or to some other person. In particular, in arriving at this conclusion, the court relied on the decision in *Papini v. Alexander Sanitarium, Inc.*, 12 Cal. App. (2d) 249, 55 P. (2d) 270. In that case the plaintiff sought damages resulting from the death of their son, who had been killed by a razor blade wielded by a fellow patient at the defendant hospital, one Boliva, who had been admitted as an "amnesia patient." In that case the appellate court reversed a judgment for the plaintiffs, holding that there was no evidence to show that the defendant knew that Boliva was suffering from "homicidal mania," that unless restrained he might voluntarily attack other patients, that he had attacked other persons on previous occasions or that he was a dangerous patient to be at large unrestrained. In this case the plaintiff relied on a number of cases in which awards were upheld for damages received by patients in jumping from windows or otherwise but, answered the court, in those cases facts were shown in evidence which indicated to the defendants that the patients involved were likely to inflict injury on themselves or others. No case was cited to this court in which a judgment was affirmed on proof that the patient was merely "delusional" or suffering from other mental disease, unaccompanied by acts pointing to violence. The court accordingly concluded that the evidence presented by the plaintiff in this case was insufficient to entitle her to recover judgment.

The judgment in favor of the defendant sanatorium was accordingly affirmed.—*Wood v. Sanarian Institution, Inc.*, 156 P. (2d) 470 (Calif., 1945).

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, Nov. 17, page 825.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF DERMATOLOGY & SYPHILOLOGY: Written. Group B. April 22. Oral. Group A and B. June 6-8. Final date for filing application is March 1. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

AMERICAN BOARD OF INTERNAL MEDICINE: Written. Various centers. Feb. 18. Final date for filing application is December 1. Asst. Sec., Dr. W. A. Wetzel, 1 W. Main St., Madison, Wis.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: Oral. Chicago, May 27. Final date for filing application is Feb. 1. Sec., Dr. T. C. Buey, 912 S. Wood St., Chicago 12.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Jan. 18-22 and Los Angeles, Jan. 28-Feb. 1. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF OTOLARYNGOLOGY: Spring 1946. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: Oral. Atlantic City, Dec. 7-8. Sec., Dr. C. A. Aldrich, 115½ First Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF PSYCHIATRY & NEUROLOGY: Oral. New Dec. 30-22. Chicago, May 24-25. Final date for filing application is February 1946. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., N.W., Washington 6, D. C.

AMERICAN BOARD OF SURGERY: Written. Part I, Spring 1946. Final date for filing application is Dec. 1. Sec., Dr. J. Stewart Rodman, 225 South 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: Written. Various centers, Dec. 9. Oral. Chicago, February 1946. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Methionine in Treatment of Toxic Hepatitis. J. H. Eddy Jr.—p. 374

Eosinophilic Lung.—According to Hodes and Wood, so-called eosinophilic lung is ushered in by lassitude, loss of appetite and fever. During the second week of illness the patient usually develops a dry hacking cough, which is worse at night. The cough becomes more severe and paroxysmal, eventually interfering with sleep. Wheezing and expiratory dyspnea develop. Many patients have symptoms of asthmatic bronchitis. Some have severe paroxysms of asthma requiring epinephrine. In rare instances an explosive asthmatic attack may be the first sign of the patient's illness. After several weeks the fever subsides, weakness gradually disappears and loss of weight ceases. The bronchopulmonary symptoms usually persist and become chronic if treatment is not instituted. Physical examination reveals hyperresonance of the chest. Sibilant and sonorous ronchi usually are present with occasional

crepitant rales at the bases. The spleen is moderately enlarged in about half of the cases. The most striking feature of eosinophilic lung is the massive eosinophilia. Roentgenograms of the chest made at the end of the second week of the febrile period reveal mottling throughout both lungs. The authors report 2 cases. They find that five injections of neoarsphenamine at four day intervals are effective in treatment. Without arsenical therapy the condition tends to persist.

The Xiphosternal Crunch.—Solis-Cohen says that in about one fifth of healthy men a crunching sound may be heard over the lower part of the sternum and the ensiform cartilage, accompanying one or both sounds of the heart and occurring chiefly during systole. The intensity of this sound is slight in a little less than half the cases, moderate in a little more than one third and pronounced in slightly more than one fifth. This crunch is often transmitted to the left, occasionally being heard as far as the apex. The crunch seems to have no pathologic significance. The importance of its recognition lies in its sometimes being regarded as an organic or congenital heart murmur or as a pericardial friction rub. Because of this sound men have been denied life insurance or have been rated up, have been refused employment, have been rejected by the armed forces and have been subjected to unnecessary treatment. Although this sound has been reported on a number of occasions from 1819 to the present time, it seldom is referred to in books or articles and is recognized by few clinicians.

Methionine in Hepatitis.—In the treatment of 30 cases of acute toxic hepatitis, most of which were caused by trinitrotoluene, Eddy employed methionine without any fatalities. At least 10 of the patients were seriously ill. This is of interest in view of the published mortality in trinitrotoluene hepatitis of 30 to 35 per cent. Of the 2 patients with trinitrotoluene hepatitis seen prior to using methionine, 1 died and the second had a prolonged illness. Many of the patients since that time have appeared to be as severely poisoned as were the first 2. Among the patients with toxic hepatitis treated with methionine the length of hospitalization varied from four days to seven weeks, with an average of thirteen days. The diagnosis was based on an analysis of the occupational exposure, physical examination, icterus index, Hanger cephalin flocculation test and urinalysis for urobilinogen and bilirubin. These examinations almost always supported one another, and they gave an excellent method of follow-up. Eddy is particularly impressed with the value of a daily urinalysis for urobilinogen and bilirubin in that it has followed the course of the illness more closely than other examinations and is easily performed. Treatment consists of bed rest, a diet rich in protein and carbohydrate and poor in fat, administration of multiple vitamin products plus added vitamin B complex and the oral administration of methionine in doses of from 3 to 8 Gm daily. Several other patients with hepatitis due to carbon tetrachloride and 2 with epidemic hepatitis are thought to have been improved by methionine.

*Transplantation of Cornea. O. I. Shershevskaya—p. 525
Specific Titration of Anti-Mercus Serum by Complement Fixation. G. A. Orlov—p. 531.

Tissue Therapy in Cutaneous Leishmaniasis.—Filatov reports the results of tissue therapy in the form of skin grafts or aloe leaf extract on cutaneous leishmaniasis. Seven cases of cutaneous leishmaniasis are reported in which either of these two modes of tissue therapy was employed. The cases demonstrate a powerful effect: tissue therapy produces in cutaneous leishmaniasis. Grafting of conserved skin and subcutaneous injections of an extract of preserved aloe leaves are equally effective.

Transplantation of Cornea.—According to Shershevskaya, of the 435 keratoplastics performed in Filatov's clinic between 1922 and 1938 success was obtained in 24.1 per cent by the use of corneas from living donors. Filatov and his school developed the use of preserved cadaver cornea. In the Odessa clinic 264 transplantations were done, using the cornea from a cadaver. The successful results in these cases amounted to 67 per cent. Filatov perfected the technic of the operation, suggested a series of new methods, constructed instruments which made this operation simpler and easier, and widely popularized keratoplasty. Her results aroused the attention of ophthalmologists. Corneal transplantation is being performed in many hospitals throughout the Soviet Union.

American Review of Tuberculosis, New York

Anatomic Studies on Human Tuberculosis: XVIII. Additional Observations on Progressive Primary Pulmonary Tuberculosis in Adults. K. Terplan.—p. 155.

Immobilization of Both Lungs.—Barach shows that, whereas in the Thunberg type of barospirometer the patient could not entirely dispense with voluntary respiration, in his apparatus this is possible. The same alternating pressure wave of 110 mm. of mercury was produced, but a partition between the head and chest end of the chamber made possible a simultaneous arrival of an equal pressure on the two surfaces of the chest wall. The arterial oxygen saturation and the carbon dioxide content were found to be normal even in patients with advanced pulmonary tuberculosis in the absence of all voluntary respiration. The ability to dispense with the recurrent impulse to breathe required training which was achieved in 1 patient in a period of forty-five minutes and in the majority of patients in three to four hours. In 10 patients who have been treated for four months and in 5 given several courses of four months each, arrest of lung movement has been obtained in all. In 4 of these patients either little improvement took place or the benefit obtained was temporary. In the remaining 6 patients significant improvement was observed. In 1 patient collapse of a large cavity took place in four months, recurred on slight activity and was closed again in a second course with fibrous tissue scar formation. Subsequently a cavity 1 cm. in diameter was seen by x-ray at the original site. Repeated individual and concentrated sputum tests have been negative for two years. The remaining 5 patients became clinically well and were discharged as able to work. Four of them are known to be at work, free from evidence of illness, with negative sputums and either without signs of tuberculosis by x-ray or with fibrotic arrest of the disease.

Central Nervous System in Uremia: Clinicopathologic Study. J. Knutson and A. B. Baker.—p. 130.
Electroencephalogram of Dogs with Experimental Space-Occupying Intracranial Lesions. G. Ulett.—p. 141.

Peripheral Nerves in Pernicious Anemia.—Foster describes pathologic changes in the peripheral nerves in 4 cases of pernicious anemia in which necropsy was performed and the results of biopsy of a peripheral nerve in an additional case. Three cases in the present series are examples of untreated pernicious anemia of many years' duration in severe hematologic

relapse at the time of pathologic examination. In all there was evidence of degeneration of the peripheral nerves, manifested by reduction in myelin sheaths and axis cylinders, degeneration of myelin, increase in Schwann cells and endoneurial connective tissue, axonal reaction changes in the ganglion cells of the posterior root ganglions and degenerative changes in the intramedullary course of afferent posterior root fibers. The other 2 patients exemplify treated pernicious anemia, with the patients in hematologic remission at the time of death. In these 2 patients, who had received liver therapy, the changes were less severe. The author concludes that the great regenerative capacity of peripheral nerves offers an anatomic explanation for the clinically observed improvement with liver therapy in some of the neurologic manifestations of pernicious anemia.

Herpes Zoster Ophthalmicus: Report of Cases and Review of Literature. A. E. Edgerton.—p. 114.

Gonorrheal Syndrome without Gonorrhea.—The triad of urethritis, conjunctivitis and arthritis, occurring in this order, in the absence of a gonococcal etiology is known as Reiter's disease. The syndrome parallels gonorrheal infection so closely that suspicion of the gonococcus is difficult to dispel. In the case reported by Lucas and Weiss a crop of small vesicles developed chiefly in the central area of the cornea five days after the onset of the conjunctivitis. These broke down shortly to form discrete superficial ulcers which showed no tendency to coalesce or penetrate and healed without residual opacification within the ensuing three weeks. In this case sulfathiazole was given without a smear having been taken. Penicillin was administered repeatedly without benefit. Ultimate therapy consisted only of hot compresses and instillations of atropine. The prognosis for the eyes is good. In the reported case all symptoms had disappeared two months after hospitalization.

Thyrotoxic Patients Treated with Thionuracil.—McGavack and his associates report studies on 10 male and 68 female patients with thyrotoxicosis who were under treatment with thionuracil. Of these 78 patients 53 had a diffusely hyperplastic and 25 a nodular type of goiter. Periods of treatment varied from two weeks to sixteen months. "Nervousness," apprehension, palpitation and loss of weight were the most common symptoms and were among the first to disappear. Exophthalmos was present in 38 of the 78 patients and was decreased under treatment in 17 instances. In 65 instances the thyroid was initially enlarged. Under treatment there was a transient decrease in size in 20 and a more prolonged increase in size in 21. The auricular fibrillation initially present in 18 individuals disappeared in 12 without other therapy than the thionuracil. Eight of the 78 patients were continued on the drug only sufficiently long to prepare them for surgery. The basal metabolic rate was depressed by thionuracil in both the nodular and the hyperplastic type of thyrotoxicosis. The average initial basal metabolic rate for the entire group was plus 46 per cent, with a low of plus 18 and a high of plus 87. The approximate time taken for the basal metabolic rate to reach plus 15 or below was three weeks. In every instance the blood cholesterol rose as the basal metabolic rate fell. Toxic reactions included 2 cases of agranulocytosis and 2 cases with severe febrile reactions, chills and urticarial skin lesions. The maintenance dose of thionuracil has varied from 0.1 Gm. to 0.4 Gm. daily, with an average of 0.23 Gm. daily for the 67 patients whose initial basal

metabolic rates were plus 30 or above. The treatment of 14 patients was successfully discontinued at the end of two and a half months in 5 cases, four months in 1, five months in 1, six months in 2, seven months in 2 and eight months in 3.

New Treatment of Renal Carbuncle.—Shearer and his associates report that a man aged 20 had had pain of moderate severity in the left lower chest and upper abdomen for two months. The pain was associated with temperature of a septic type. The patient stated that four days before the onset of pain he had had several boils on his face and two carbuncles in the right cervical region. Gradually, pronounced tenderness became apparent in the left costovertebral region. Intravenous pyelography revealed some compression of the calix of the left kidney, which suggested a left perirenal abscess. At surgery an abscess was not present; further studies indicated an expansile mass in the lower portion of the kidney. At a second operation the kidney was freed to the hilar structures anteriorly and posteriorly, an aspirating needle was passed into several suggestive areas and purulent material was obtained from a site deep in the substance of the kidney at the junction of the upper two thirds and lower one third. Ten cc. of thick purulent material was released and a No. 16 F. catheter was sutured

into the cavity. Bacteriologic examination of this material established the presence of a hemolytic *Staphylococcus aureus* in pure culture. One Penrose drain was placed at the upper pole of the kidney and a second at the lower, the wound was closed in layers, 200,000 units of penicillin was administered intramuscularly daily, the abscess cavity was lavaged twice daily with 5 cc. of a solution of penicillin containing 250 units per cubic centimeter and rapid sterilization was effected.

Aneurysm of Renal Artery.—Levine observed a true aneurysm of the renal artery in a woman aged 59. The laminographic method of examination as first suggested by Wilhelm was particularly helpful in establishing the diagnosis. The aneurysm was approached transperitoneally. It was felt that in dealing with a friable aneurysm it might be well first to ligate the renal vessels before mobilizing the aneurysm and the kidney. As a precautionary measure, tapes were passed under the vena cava above and below the renal vessels. The transperitoneal approach is also to be preferred if repair of the aneurysm is contemplated. The patient has been examined at regular intervals for six months after the operation. During this time she has been free from all pain and has felt well.

Treatment of Tonsillitis.—Clodfelter reports 400 cases of streptococcal sore throat selected from more than 3,000 acute upper respiratory infections of such severity as to require hospitalization. In 41 of the 175 treated with large doses of sulfonamides the course was similar to that of the untreated cases and they were discharged on the fifth or sixth day. The secondary rise in temperature was present in 134 of the sulfonamide treated cases. The greatest number of discharges from the hospital in this group was on the tenth day and the average number of hospital days was 9.7. Sulfathiazole and sulfadiazine were used in about an equal number of cases without any appreciable difference in the two drugs. The use of sulfonamides in the treatment of severe cases of acute tonsillitis results in a prompt drop in the temperature with some relief from symptoms. But there is usually a secondary rise in temperature at the time untreated cases are being discharged. The number of hospital days is increased from 5.3 to 9.7. The patients did not feel as well on the tenth day as the untreated ones did on the fifth. It seems highly suggestive that the use of sulfonamides in the treatment of acute streptococcal tonsillitis is not only without benefit but actually detrimental to the welfare of the patient.

Sulfaguandine in Dysentery.—Wegman and his associates studied the value of sulfaguandine in young children. Immediately after admission a rectal swab culture was made and after this a culture was made of the first stool passed. Administration of sulfaguandine was then begun with a daily dose of 0.1 Gm. per kilogram of body weight. Half of this daily dose was given on admission, followed by one fourth of the daily dose every six hours. The dosage was reduced to half the amount when diarrhea had been absent for two days and was discontinued entirely after four days without diarrhea. Forty of the children had had at least one culture positive for *Shigella*. Flexner V, W, Z or Sonne. Other varieties of *Shigella* were not encountered. Of the culturally positive cases, 23 were treated and 17 were untreated controls. The treated cases, regardless of the duration of the disease before treatment was begun, tended to terminate within a few days time, while a good proportion of the control cases lasted two weeks or more. In the 37 patients originally included in the study, but in whom cultures were never positive, there was little difference between the treated and the control cases. These observations are at variance with several reports in the literature which have indicated the value of sulfaguandine even in the absence of positive cultures. The contrast in this study, however, adds to the evidence that sulfaguandine must have a specific effect on *Shigella*. In the cases with positive culture, treatment with sulfaguandine effected improvement both in terms of the duration of the diarrhea and in terms of the duration of the infection.

Intramuscular Injection of Aluminum Penicillin.—

Results obtained in treating patients with gonorrhea indicate that a single injection of 50,000 units or more of aluminum potassium sulfate and penicillin mixture will maintain a therapeutic level from six to nine hours. Two injections of 50,000 units at nine hour intervals would be the minimum dosage to maintain assayable levels for eighteen hours. In several cases of gonorrhea cures were obtained at low level dosage, but the number is far too few to justify conclusive statements. The practicability of the use of aluminum penicillin mixtures in decreasing both dosage of penicillin and number of injections is evident. Subsequent tests with aluminum penicillin and other therapeutic agents may reveal that syphilis as well as gonorrhea may be treated by general practicing physicians without hospitalizing the patient in rapid treatment centers.

Nebulized Penicillin in Respiratory Infections.—Results with nebulized penicillin have been so much superior to those with sulfonamides that there is no need to use the latter with the attendant danger of sensitization and possible death. Thus far no complications have been experienced with penicillin. A saline solution containing 500 units per cubic centimeter seems to give the best results. An oxygen tank with a flow meter and humidifier is connected by a rubber tube to a DeVilbiss Nebulizer No. 40. Two cc. of penicillin solution is placed in the glass nebulizer, and an oxygen flow of 4 liters is set. The patient is instructed to hold the nebulizer between the teeth and breathe through the mouth. The treatment usually takes twenty minutes and is given once a day. In acute tonsillitis, laryngitis and bronchitis the results are startling. One, two or three treatments gives complete relief from fever and other symptoms. The subacute type of infection, such as the streptococcal pneumonia, will respond to six to twelve treatments given once a day. The chronic infection will require twenty to sixty treatments once daily. In cases of chronic infection the sputum will be reduced, the temperature will return to normal or nearly so, the toxic symptoms will diminish and a feeling of well being will be reestablished. Virus pneumonia will also respond to this method of treatment even where parenteral injection of penicillin has failed.

Whooping Cough Vaccine in Nursery Groups.—McFarlan and his associates assessed the prophylactic value of pertussis vaccine by comparing inoculated children and control children. Over 600 susceptible children of 6 months to 3 years of age attending welfare clinics and wartime day nurseries in Oxford City, and 110 evacuee children of 6 months to 3 or 4 years of age distributed in eight residential nurseries in Oxfordshire, Berkshire and Buckinghamshire were divided into "inoculated" and "control" groups by methods designed to render the two groups similar in every respect other than inoculation. The inoculated children were given either two doses of pertussis vaccine at a four weeks interval or four doses at intervals of one, one and four weeks. The total dosage ranged from 40,000 to 100,000 million organisms, corresponding to an American dosage of about 120,000 to 300,000 millions. Whooping cough occurred sporadically in Oxford City during the succeeding eighteen months and broke out in four of the residential nurseries two weeks to nine months after the last inoculation. Significant differences were not observed in the incidence or severity of whooping cough between the inoculated and the control children. In Oxford City 12.5 per cent of 327 inoculated and 14.1 per cent of 305 control children developed definite whooping cough. In the residential nurseries the corresponding figures were 55 per cent of 33 inoculated and 63 per cent of 30 control children. The evidence obtained from this investigation lends no support to the view that pertussis vaccine is of value in the prophylaxis of whooping cough; and it is suggested that the use of this vaccine should be discontinued till some positive evidence of its value is obtained.

Polyneuritis After Jungle Sores.—Ward and Mason say that in a recent campaign in the Burmese jungle many of the British and Indian troops developed multiple indolent ulcers, commonly known as "jungle sores." Some of those who had suffered from jungle sores contracted a peripheral neuritis later. Of 21 patients 11 were admitted complaining of symptoms referable to their neuritis, 9 because of malarial relapse and 1 with jungle sores. All had suffered from jungle sores but, except for patient 19, the ulcers were healed at the time of admission. Sixteen patients reported blurring of vision as the first symptom of nervous involvement. The average duration of blurred vision was four weeks. All patients noted disturbance of sensation. In 4 cases it synchronized with blurring of vision, but in the remainder it occurred three weeks later. Sensory symptoms consisting of tingling, numbness and coldness of the extremities were often severe enough to make the men report sick. In the milder cases these paresthesias were the only complaints; however, others later complained of difficulty

in walking and writing. The picture in its most severe form was completed by progressive weakness of the limbs, spreading to involve hips and shoulders. In addition anesthesia of the extremities, astereognosis and ataxia were present. From a shuffling walk with feet apart the gait deteriorated until walking was impossible. Examination of the nervous system in these cases showed the characteristic signs of a polyneuritis. Eleven of the cases were mild. In 7 moderately severe cases the disability was sufficient to impede the patient's everyday life. Only 3 patients became bedridden. The polyneuritis was not influenced by the vitamin B complex. Moreover, the nutrition of all patients was good. The author suggests that a toxin, elaborated by bacteria infecting the ulcers, was the responsible agent. He thinks it most likely that the polyneuritis followed a diphtheritic infection of the jungle sores.

Protozoan Parasite of Nervous System.—Veeraraghavan encountered forms in the midbrain of guinea pigs experimentally infected with rabies which have not, apparently, been previously described. The peculiar forms have been investigated over the past six years. The conclusion was reached that they are due to the presence of a parasite, probably protozoan in character, which is specific to the central nervous system. It has not been possible to identify this parasite with any previously described, such as *Encephalitozoon cuniculi*, or any known species of toxoplasma. The protozoan parasite was first encountered in the midbrains of guinea pigs infected with the jackal strain of rabies virus. The parasite, with the exception of certain cystic forms of doubtful significance, invariably occurred in the cytoplasm of nerve cells, particularly those ventral to the central canal of the midbrain. In a few cases, parasites were found also in the Purkinje cells of the cerebellum and in the hippocampus major. The smallest forms of the parasite encountered were minute "spores." They were regularly found in the midbrains of the naturally infected dogs and jackals and in the brains of guinea pigs inoculated with suspensions of their brains. The next stage of the parasite appeared to be the "ring" form. It might be round or oval, and it was variable in its position within the vacuole. Certain forms resembling the accolé forms of the malaria parasite were occasionally found. These consisted of a crescentic bridge of cytoplasm with a rounded chromatin dot. In slightly older forms the chromatin mass was slightly larger, the protoplasm was thickened and the parasite assumed a variety of shapes. Segmentation of the chromatin appeared to be the next stage in the development of the parasite. In the segmenting forms the protoplasm appeared to be a solid mass with a varying number of chromatin dots. No evidence was found to suggest that the various forms of the parasite were the result of alterations in the constituents of nerve cells. The possibility of the parasite being a natural infection common to dogs and jackals, unconnected with rabies infection, was investigated. Neither parasites nor Negri bodies were ever encountered in animals

without rabies. Certain stages in the life cycle of the protozoan parasite described appear to be "filtrable"; it has been possible to produce evidence of infection in experimental animals by the inoculation of brain suspensions passed through Berkefeld V and N candles. The protozoan parasite appears to be a specific infection of the central nervous system, and in spite of exhaustive searches it has never been observed in other organs and tissues. It was not observed except in association with natural or experimental rabies infection. The suggestion has been put forward that Negri bodies may represent a stage in the life cycle of the parasite.

Autolytic Enzymes in Bacteriolysis by Penicillin.—Todd shows that autolysis plays a large part in the lysis which occurs when organisms are killed by penicillin; they do not however entirely exclude the possibility that penicillin may have bacteriolytic properties apart from autolysis. The rate of lysis of bacteria in cultures containing penicillin depends on the production of autolysin. Organisms which produce large quantities of autolysin are lysed rapidly; those which produce less autolysin are lysed more slowly, while those which produce no autolysin are probably not lysed at all. Living bacteria are resistant to autolysis; they become sensitive when killed by penicillin, by heat or by suspension in isotonic solution of sodium chloride. The most rapid bactericidal action of penicillin occurs when organisms are at their maximal rate of multiplication. The rate of bacteriolysis in cultures containing penicillin is therefore governed by both the rate of multiplication and the production of autolysin. Certain bacteria which produce little autolysin are killed by penicillin without undergoing bacteriolysis; they are then rapidly lysed if autolysin is added to the dead culture. The most probable explanation of bacteriolysis in cultures containing penicillin is that the organisms are first killed by penicillin and then autolysed.

Intestinal Mucosa in Ulcerative Colitis.—The course of ulcerative colitis with its tendency to spontaneous remissions and relapses led Gill to consider that in some cases at least the condition might be a deficiency disease. Preliminary inves-

tigations suggested that the missing hypothetical factor might be present in or produced by the intestine. Feeding experiments in 1 case over several years showed that remissions could be induced regularly by giving uncooked pig's small intestine by mouth. Relapses always followed when this treatment was stopped. Remissions have also been induced in other cases in which similar raw material was given; others, however, have shown no response. Pig's small intestinal mucosa, dried and defatted, given by mouth in powder form, has also induced remissions in some cases. Those patients who respond relapse when the treatment is stopped. Of the dried mucosal preparations tried, one has little or no effect, whereas the other appears to be as effective as the raw material. Experiments with a parenteral extract have so far been unsuccessful. The results obtained with this treatment do not appear to be coincidental or psychologic: they are compatible with the deficiency theory advanced, but a local effect in the colon is not yet excluded. The author thinks that the term "ulcerative colitis" must cover more than one disease, or that more than one etiologic factor is responsible for the syndrome, since it is impossible to forecast whether or not a given case will respond to this form of treatment.

Prognosis of Essential Hypertension.—One hundred patients with hypertension studied in 1936 to 1938 were reexamined in 1943 with consideration of the prognostic value of the earlier pathologic findings in the cardiovascular and renal systems. Fifty-two patients had died, 44 were still living and 4 had not been traced. Of the 44 survivors, 36 were women and 8 were men. The cause of death of 2 patients was unknown, while 13 died of cardiac insufficiency (26 per cent of the number of deaths), 9 died of myocardial infarction (18 per cent of the deaths), 19 (38 per cent) died of apoplexy and 3 (6 per cent) died of uremia. While the prognosis of myocardial infarction and uremia may be difficult, as they show no distinct relation to the earlier findings in the cardiovascular and renal systems, cardiac insufficiency exhibits a distinct correlation to the size of the heart and to the electrocardiographic alterations (left ventricular hypertrophy). The apoplexies show especially clear relationship to the height of the blood pressure, both the systolic and particularly the diastolic. Nearly one third of those with systolic pressure above 200 and more than one third of those with diastolic pressure above 125 died of apoplexy during the observation period. The surgical treatment of hypertension may in these groups be considered from the standpoint of prophylaxis of cerebral hemorrhage. Reinvestigation of the blood pressure showed that it was increased in only 5 patients. Most often it is stationary and in one fourth of the patients distinctly reduced, while in 2 patients it has become normal. Although in 1 patient there has developed nephrosclerosis, the 39 patients reexamined show primarily a slow development of hypertensive heart disease, sometimes with myocardial infarction and angina pectoris, sometimes with cardiac enlargement, this disease being electrocardiographically characterized by development of left ventricular hypertrophy in different stages.

Traumatic Cardiac and Respiratory Neurosis.—Heckscher presents a survey of a series of 22 patients suffering from the sequelae of thoracic contusions. Twenty of these patients were men and 2 were women. They were between

the ages of 33 and 60. Most of the complaints were not caused by any organic heart lesions but by the bruises inflicted on the chest wall and by a traumatic cardiac and respiratory neurosis. The symptoms of this traumatic neurosis were very much like the symptoms of the nontraumatic cardiac and respiratory neurosis. Conspicuous subjective symptoms were dyspnea on exertion or paroxysmal shortness of breath at rest, a feeling of oppression, palpitations, pain in the chest or in the back, anxiety and in some cases pronounced hypochondriasis or a real anguish. The objective symptoms were those which together form the pathognomonic triad of pulmonary emphysema: (a) the respiration changed from abdominal to mixed or purely thoracic type, (b) the changed posture, i. e., postural anomalies and (c) widening of the thoracic cavity and expansion of the lungs. In addition some patients presented the special neurotic type of respiration with sporadic, forced inspirations followed by delayed return to normal level. Some patients presented a mutual interdependence of pulse rate and respiration, both being influenced decidedly more by psychic alterations than by physical exercise, so that paradoxical reactions to tests of heart function could be seen, quite unlike the reactions of patients suffering from organic heart failure. The pains in the chest or back presented by the majority of the patients were partly caused by the bruised muscles of the chest wall and the back and partly by the functional changes in the muscles overstrained by static work. As these patients had displayed habitual anomalies of posture even before the accident, it is likely that they have contributed to the development of the disease. Differential diagnosis between functional and organic disorders of the heart must be based on the absence or the presence of symptoms absolutely pathognomonic for an organic heart disease. An erroneous diagnosis of organic heart failure may lead to a lasting invalidism of the patient. Physical therapy with exercises instituted soon after the accident may be of considerable help in preventing fixation of the chest, eliminating at the same time the tendency to persisting functional disturbances.

Gastritis.—Holtermann and Myhre found that gastritis accompanied duodenal ulcer in every case. In nearly half of their ulcer cases the gastritis was of hypertrophic type. In certain cases gastritis may consist only of a reddening and mild edema caused by hyperfunction. After a dietary course ulcer patients with hypertrophy and superficial catarrh may be improved with regard to the superficial catarrh, but hypertrophy will persist in the form of thickening and irregularity of the folds. Gastritis associated with duodenal ulcer was generally more pronounced and diffuse than that in gastric ulcer in which the mucosa may present a normal aspect after a successful dietary course. The subjective symptomatology of gastritis varies considerably. Sedimentation tests were performed in 135 cases. These tests revealed that an increased amount of mucous sediment formed within twenty-four hours in the gastric juice of fasting patients is to be considered as an important objective symptom. A series of nitrogen determinations in the gastric juice from fasting persons showed little correlation with the gastroscopic and roentgenologic findings and also with the results of the sedimentation tests. Nitrogen determination is of little value as a diagnostic sign. Gastroscopy is the most reliable diagnostic method and may likewise aid in classification. The gastritis may also be demonstrated roentgenologically. Better information will be obtained when small amounts of contrast medium are spread evenly over the mucosa. The method used by the authors consists in aspirating the gastric juice of the fasting patient with a duodenal tube during fluoroscopy. The mucosal folds must not be separated by outside pressure, and the supine position of the patient is preferable to the prone position. An irregular course of the folds often suggests gastritis, especially if it is associated with a certain degree of thickening. To evaluate the thickening of the folds, the form and size of the stomach are to be considered likewise. There is a fair chance of a correct diagnosis with an ordinary angular stomach. Negative roentgenologic findings do not exclude gastritis. Differential diagnosis between hypertrophic gastritis and superficial catarrh and atrophy should not be based on roentgenologic findings.

Book Notices

A Manual of Surgical Anatomy. Prepared Under the Auspices of the Committee on Surgery of the Division of Medical Sciences of the National Research Council. By Tom Jones and W. C. Shepard. Cloth. Price, \$5. Pp. 195, with illustrations. Philadelphia & London: W. B. Saunders Company, 1945.

This is the last volume of the *Military Surgical Manuals* edited by the Committee on Surgery of the National Research Council for medical officers of the armed forces. While victory has fortunately diminished the opportunities for its use as a field manual, it will have a much more lasting value than its predecessors in the series. It was originally planned as a concise atlas of applied surgical anatomy of a format that would make it easy to carry and use under campaign and battle conditions. It is a visual presentation of anatomic regions most likely to be of importance to the surgeon caring for lesions produced by weapons of warfare. The material for presentation has been well selected from that point of view. The illustrations are new, having been redrawn from older cuts or evolved specially for this manual. They are line drawings, in many of which color has been skilfully used to aid greatly in the visual effects. The drawings are large enough to be easily studied, while the labels in English terminology are printed in large type so as to be clearly readable. The contents are arranged in four sections: part I, the head and neck; part II, the trunk-thorax, abdomen and pelvis; part III, the upper extremity; part IV, the lower extremity. Surgical approaches presented with each of these sections show with accuracy and clarity the approved avenues of approach used in the surgery of today. The incisions shown for operations on the thorax are especially valuable, as they were developed for this book and brought together for the first time in these illustrations. It is hoped that in the next edition the abdominal wall will receive similar treatment. There is an explanatory index in which are listed and defined the anatomic structures shown in the charts; the Standard English and B. N. A. terms are both given when there is a difference of anatomic name. That the book is the result of the collaboration of Mr. Tom Jones and Mr. W. C. Shepard in a field of surgical illustrations assures immediately a work of a high quality, and they are to be congratulated on the result of their labor, carried out with great zeal and haste in the face of national emergency. While the urgency for the manual has disappeared, the need for such a manual in civilian surgery remains. Anatomy cannot be learned from books, but such an atlas serves always as a convenient refresher to the surgical mind, and the surgical approaches are a matter of interest to all surgeons. This manual is heartily recommended to students of surgical anatomy, to those studying surgery and to those practicing the surgical arts.

The Principal Nervous Pathways: Neurological Charts and Schemas with Explanatory Notes. By Andrew Theodore Rasmussen, Ph.D., Professor of Neurology, Department of Anatomy, University of Minnesota Medical School, Minneapolis, Minn. Third edition. Cloth. Price, \$3.50. Pp. 73, with 28 illustrations. New York: Macmillan Company, 1945.

This excellent monograph of nervous pathways should be in the possession of every neurologist, neurophysiologist and neurosurgeon. Former editions have proved on many occasions to be most helpful in cerebrospinal localization because the author has followed the concept of correlation of function and structure in the central nervous system, which should be the method of teaching. The illustrations speak for themselves. The work is the best of its kind for ready reference and study and is highly recommended.

A Manual of Ophthalmology for Medical Officers. By Lt.-Col. B. W. Rycroft, M.D., D.O.M.S., F.R.C.S., Surgeon and Dean, Royal Eye Hospital, London. Cloth. Price, \$2.50. Pp. 95, with 59 illustrations. New York & London: Paul B. Hoeber, Inc., 1945.

This book is an outline presenting in brief form the methods of examination and the common diseases of the eyes and eye injuries seen in military practice by the general medical officer. It is of little value to the practicing ophthalmologist. It might be useful to the industrial surgeon who does not have a consulting ophthalmologist available.

Mental Disorders in Later Life. Edited by Oscar J. Kaplan. Cloth. Price, \$5. Pp. 436, with 14 illustrations. Stanford University: Stanford University Press; London: Oxford University Press, 1945.

The increasing number of books dealing with the problems of old age bears testimony to the growing interest in the subject. Dr. Kaplan well describes the nature of this book in the preface when he says that it does not pretend to be an exhaustive treatment of the subject of mental disorders in later life but "is rather a collection of essays selected to indicate the level of present achievement in this area. . . In this book we see the pattern of future attack upon the mental diseases of later life. . . through the close collaboration of psychiatrists, statisticians, physiologists, sociologists and psychologists." Seventeen contributors have written separate chapters, which cover virtually all phases of the subject. Of particular interest are the chapters on the physiologic and the psychologic aspects of aging, on the neuroses of later maturity, on the senile psychoses and cerebral arteriosclerosis, on psychotherapy in the older person and on mental hygiene in later maturity. This book sounds a more optimistic note for the aging and aged patient than most publications in this field. It emphasizes the point that much more can be done for the aging than for the aged and that the time to prepare for old age is while one is still in the vigor of maturity. The book is a mine of information for the physician who wants to learn more about recent important advances that have been made in understanding the senescent and the senile patient.

Klinische und erbblologische Untersuchungen über die Heredoataxien. Von Torsten Sjögren. Acta psychiatrica et neurologica Supplementum XXVII. Paper. Price, 15 Dan. Kron. Pp. 200, with 6 illustrations. Copenhagen: Ejnar Munksgaard, 1943.

This is a monograph on the hereditary ataxias written by the author from material studied in Göteborg and Stockholm. There are six chapters: the material and its classification, the collection of the author's cases, clinical analyses, hereditary studies, summary and bibliography. This is an excellent contribution in relation to genealogical and clinical studies in 188 cases. Three thousand persons were studied from the hereditary point of view.

The Chemical Formulary: A Collection of Valuable, Timely, Practical Commercial Formulae and Recipes for Making Thousands of Products in Many Fields of Industry. Volume VII. Editor-in-Chief: H. Beckett. Cloth. Price, \$6. Pp. 474. Brooklyn: Chemical Publishing Co., Inc., 1945.

As stated in the preface, the Chemical Formulary is a collection of valuable and practical formulas and recipes, compiled with the assistance of many contributors from numerous fields of industry. As in other volumes the methods of preparation are given in many instances, which is of considerable aid. The book is divided into many parts relative to the different types of formulas. This volume, with its various new data and the enlargement of the directory of sources of chemicals and supplies, will prove to be of great value in the technical field. However, the book lends little value to the physician but a hand to medical quackery. It is to be commended in that it makes no claims for remedial action and thereby assumes no responsibility for its therapeutic uses.

Diseases of the Nervous System Described for Practitioners and Students. By F. M. R. Walshe, O.B.E., M.D., D.Sc., Physician in Charge of the Neurological Department, University College Hospital, London. Fourth edition. Cloth. Price, \$4.50. Pp. 360, with 51 illustrations. Baltimore: William Wood & Company, 1945.

This tremendously practical and easily understandable book should become more popular in the medical schools of the United States. It is made up of twenty-nine chapters divided into two parts. Part one takes up the general principles of neurologic diagnosis and part two gives a descriptive account of the more common diseases of the nervous system. The book is written for use by the student and the general practitioner. It should be in the office of all medical men. The author has written his book from a practical standpoint so that the reader will not have to remember individual symptoms of each nervous disease but has to learn those symptoms which occur in lesions of various structures or systems. This book is highly recommended.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

THE THIRD STAGE OF LABOR

To the Editor:—Is there really a third stage of labor or is it simply a continuation of the second stage? Is it not a fact that with the final contraction which expels the fetus the placenta is completely severed from the uterine wall and then acts only as a foreign body in the uterus and should be manually expelled at once?

P. V. Janse, M.D., Algona, Iowa.

ANSWER:—The third stage of labor comprises two phases, separation and expulsion. The normal mechanism rarely separates the placenta completely as the baby leaves the uterus. In many instances this undoubtedly happens, so that the phase of separation can be designated as part of the second stage. More often partial separation takes place at the time of expulsion of the fetus. Complete separation is accomplished by resumption of uterine activity. The expression of the placenta should not take place until evidences of complete separation are apparent. Premature attempts at the expression of an incompletely separated placenta may lead to uterine atony and excessive bleeding. Mismanagement of this phase of the third stage is the most common cause of postpartum hemorrhage.

The ineffective third stage of labor has led to the use of oxytocic drugs during this period. To accomplish complete separation of the placenta at the time the baby leaves the uterus, M. Edward Davis (*The Use of Ergonovine in the Placental Stage of Labor*, *Am. J. Obst. & Gynec.* 43:775 [May] 1942) has suggested the administration of 0.2 mg. of ergonovine intravenously just as the head is being delivered. Twenty or thirty seconds should intervene before the rest of the baby is born. The powerful uterine contraction initiated by the ergonovine results in the immediate and complete separation of the placenta, as the placental site shrinks because of the uterine contraction. Expression of the placenta should follow immediately. Improper timing of this procedure may result in the incarceration of the placenta in a contraction zone at the lower portion of the uterus.

This artificial conduct of the third stage has had extensive clinical experience during the last five years. It has resulted in a great decrease in the blood loss during placental separation, as well as in a definite reduction in the complications associated with the placental stage.

CESSATION OF MIGRAINE DURING PREGNANCY

To the Editor:—A woman who has been subject to migraine become pregnant for the first time after nineteen years of married life and delivered a normal baby. The baby is now 3 weeks old and the headaches, after absence during the pregnancy, have returned.

J. Huntley Boyd, M.D., Trenton, Mich.

ANSWER:—Among women with migraine it is the rule for headaches to occur in relation to menstruation, to be absent during pregnancy and to fade out at the menopause. These circumstances point to the importance of the sex hormones in causing migraine attacks and suggest that appropriate endocrine therapy or procedures which would neutralize the effect of the menstrual cycle on the sympathetic nervous system would be of value in the treatment of these patients. Unfortunately there do not seem to be any consistently encouraging reports of endocrine therapy. Clinical research on this subject is long overdue.

EDIBLE FROGS

To the Editor:—We have in our locality two species of frog: One is the green frog and is highly esteemed as food; the other is the leopard frog, which has no green coloring. As youngsters we referred to the latter variety as the "stink" frog. The habits of the two varieties so far as I know appear to be identical. Is there any reason why the leopard variety would not be a safe article of food?

W. C. Hensyl, M.D., Berwick, Pa.

ANSWER:—The leopard frog is eaten in several parts of this country. There seems to be no reason for its being less highly esteemed than the green frog. The other large species of the genus *Rana* are also edible.

Wright, A. H.: *Frogs: Their Natural History and Utilization*, U. S. Bureau of Fisheries, Doc. 888, 1920, pp. 1-44.

MECHANISM OF DIABETIC COMA

To the Editor:—It has been stated that a lack of insulin is the fundamental cause of diabetic coma. The lack of insulin causes a reduced glucose oxidation throughout the body. This reduced glucose oxidation is particularly manifest in those organs which burn glucose practically exclusively for energy purposes such as the brain. For this reason it would be proper to state that the immediate cause of diabetic stupor and coma is a reduced glucose oxidation by the brain. A similar mechanism is present in hypoglycemic coma, namely a reduced glucose oxidation resulting from the reduced delivery of glucose to the brain. The final common effect on the brain will be the same, therefore, in diabetic and hypoglycemic coma, and the common factor is a pathologically reduced glucose oxidation. Diabetic coma may not be attributed to ketone bodies, because these are not always present in pathologic amounts. Further, they may be present in pathologic amounts in diabetes without coma. The ketosis is secondary to the deranged carbohydrate metabolism and disappears when the deranged metabolism is restored with insulin. Ketosis may also be present in hypoglycemic states because of the reduced glucose oxidation. Reduced glucose utilization is always accompanied by reduced oxygen consumption. This has been shown by several investigators on both man and the dog as well as on an isolated tissues. Cells consume oxygen in proportion as they utilize glucose. Restoration of glucose oxidation in diabetic coma by insulin is apparently brought about by glycogen synthesis in the liver. The liver in diabetic coma has a low glycogen content. With insulin the glycogen stores are built up. It is believed by some that such glycogen breaks down, yielding gamma glucose, a form which is readily oxidized by the brain and other tissues. The blood sugar in untreated diabetic coma may be said to exist chiefly as alpha-beta glucose, a form which is not readily oxidized by living cells. Insulin brings about recovery by taking glucose from the blood, bringing about glycogen synthesis in the liver, which then breaks down to yield the more readily oxidizable form, namely gamma glucose.

Benjamin P. Sandler, Lieutenant Commander (MC), U.S.N.R.

ANSWER:—There are several erroneous premises and conclusions in the foregoing:

1. It cannot be said that diabetic coma and hypoglycemic coma are both the result of the failure of the brain to burn glucose. For, while this is true in the latter condition, because of a failure of delivery of adequate amounts of glucose to the brain as a result of the low blood sugar levels, it has been shown (Himwich, H. E., and Nahum, L. H.: *The Respiratory Quotient of the Brain*, *Am. J. Physiol.* 101:446 [Aug.] 1932) that in the total absence of insulin the brain is able to metabolize carbohydrates and maintain its respiratory quotient at 1.0. The wide differences in symptomatology of diabetic and hypoglycemic coma lend support to a difference in etiology of the two.

2. It is indeed doubtful that diabetic coma can develop in the absence of ketosis. The ketone bodies certainly cannot be excused from an important etiologic role in diabetic coma simply because they may be present at times without the occurrence of full blown diabetic coma. Their role in producing the disturbed acid-base relationship, acidosis and dehydration is well known. At least acetoacetic acid is believed to be toxic per se (Best, C. H., and Taylor, N. B.: *The Physiological Basis of Medical Practice: A University of Toronto Text in Applied Physiology*, ed. 3, Baltimore, Williams & Wilkins Company, 1943, p. 963). The depressed consciousness which may occur in the clinical syndrome we call diabetic coma is probably the result of several interdependent metabolic derangements, the sum of which, rather than any one singly, is responsible.

3. Ketosis apparently is not due to an inability of the tissues to oxidize glucose but rather seems to occur in conditions in which liver glycogen is seriously depleted (Best and Taylor: *The Physiological Basis of Medical Practice*, p. 1019. Peters, J. P.: *A New Frame for Metabolism*, *Am. Scientist*, 31:36 [Jan.] 1943). Thus it is a finding in starvation and in phlorhizin diabetes, in which liver glycogen drops very low and energy requirements must be supplied largely by utilization of fats. Furthermore, in the depancreatized animal large doses of glucose administered intravenously will decrease ketonemia and ketonuria concomitant with storage of glycogen in the liver in spite of the fact that the glucose probably is not being burned by the peripheral tissues (Mirsky, I. A.; Heiman, J. D., and Broh-Kalm, R. H.: *The Antiketogenic Action of Glucose in the Absence of Insulin*, *Am. J. Physiol.* 118:290 [Feb.] 1937).

Ketosis is not a finding in hypoglycemia, except in rare instances, as liver glycogen is not depleted in this condition. It is a rare possibility in renal diabetes with a very low renal glucose threshold (resembling the phlorhizinized animal [Wierzechowski, M.: *Intermediate Carbohydrate Metabolism: Vital Action of Glucose in Phlorhizin Diabetes*, *J. Biol. Chem.* 73:445 (June) 1927]) and in von Gierke's disease. In the former condition, depletion of liver glycogen occurs before ketonuria and hypoglycemia appear, and in the latter the liver, though filled with glycogen, is functionally without glycogen, as the glycogen present cannot be utilized. Infiltration of the liver with fat in the latter condition is common in the glycogen-depleted liver.

4. The question whether insulin acts to produce an active, or gamma glucose is still completely hypothetical. As far as can be determined, there is no definite evidence on this point.

PERSISTENT URINARY OBSTRUCTION AND INFECTION

To the Editor:—A man aged 28 has been under treatment for urinary symptoms of about two and a half years' duration. The symptoms began about January 1943 while at sea, with sudden inability to void. He passed a urinary calculus, and this was followed by pyuria. Examination of the kidney, ureter and bladder revealed an additional renal calculus in the right inferior calyx and a right ureteral dilatation plus a right hydronephrosis. Further studies in the next few months revealed a urethral stricture and chronic cystitis. He was treated with many cystoscopies and lavage plus several courses of sulfathiazole and sulfapyridine. His urgency, frequency and dysuria improved slightly. He was readmitted to a navy hospital November 1943 to May 1944. During this stay he underwent cystoscopy; at this time films revealed contraction of the vesical neck, and a transurethral resection of the prostate was done. Following this he passed the previously mentioned stone, but considerable difficulty in urination remained. He became icteric, apparently as a result of sulfonamide medication. Liver function tests showed "considerable hepatic damage." The cystitis appeared to be due to *Escherichia coli*. Courses of penicillin, tyrothricin lavage and mandelic acid were of no avail. Urethral dilations have been done, but his urinary frequency (about every fifteen to thirty minutes) and severe tenesmus remain. The urine is full of white blood cells with scattered red blood cells; albumin is 2 plus. The blood cells appear normal. Several cultures of the urine showed hemolytic streptococci and nonhemolytic streptococci; others showed *Alcaligenes fecalis*. Is there anything further that can be done for this man? Of course the question of the newer drugs such as streptothricin has been brought up. Is it possible that one of these may be tried safely? It is felt that further courses of sulfonamides are inadvisable, since he has had severe reactions to them.

Jerome S. Davis, M.D., P. A. Surg., U. S. P. H. S. (R.)

ANSWER.—Although a bladder neck obstruction has been found and presumably removed the patient undoubtedly has further obstruction at that point as well as having an obstructing hydronephrosis; both factors are responsible for the persistence of this man's infection.

There does not seem to be any rationale to the continuation of all sorts of urinary antiseptics in a patient such as the one described. Thorough investigation of the cause of the obstruction should be made, with its relief, if possible, after which thorough prostatic and seminal vesicular massage should be given together with medicaments which would tend to keep the urine acid. Perhaps even this treatment will not be completely curative.

TINNITUS

To the Editor:—A white man aged 28, weighing 230 pounds (104 Kg.), 73 inches (185 cm.) tall, has had a constant moderately high pitched tinnitus in the right ear for the last six weeks. The drums and external auditory canals are normal except for a slight dilatation of the small blood vessel on the right drum running over the handle of the malleus. Both eustachian tubes are open and click on swallowing. Hearing does not seem to be impaired, but no audiometer tests have been done. A small amount of soft wax present was syringed out, but the tinnitus did not stop. The eyegrounds are normal and no scotomas, headaches, vertigo or vomiting have been present. Neurologic examination revealed no abnormalities. On clenching the teeth tightly the volume of the tinnitus is increased. X-ray of the teeth in the right upper jaw is normal, but several large cavities have been recently filled with silver. The blood count, urinalysis and blood pressure have been normal.

Oscar J. Bolchum, M.D., Detroit.

ANSWER.—In the absence of other evident causes and in the presence of an apparently normal middle ear, as shown by the absence of important changes in the drum membrane, no satisfactory solution is possible in the problem presented without a careful testing of the hearing ability. The two most likely causes would be auditory nerve deafness and otosclerosis. Each can be diagnosed by tuning fork and audiometric examinations. There are cases of tinnitus in which no great loss of hearing is demonstrable on early examination. Only after a number of tests and the passage of some time can it be possible to assign the tinnitus definitely to a lesion in the hearing apparatus.

PASSAGE OF PENNY FROM STOMACH

To the Editor:—A boy aged 3 years has had a penny in his stomach for about two weeks. I have had him on a high residue diet, but the penny has not yet passed. The presence of the penny in the stomach does not seem to be causing him any inconvenience, but I am afraid that it may if it is allowed to remain over too long a time. At what age will the outlet of the stomach become adequate to allow the passage of the penny?

J. A. Orris, M.D., Windber, Pa.

ANSWER.—In all probability there is sufficient spasm of the outlet of the stomach to prevent the penny from passing. X-ray observations of stomachs of children at this age indicate that they are not so narrow as to prevent the passage of a penny. The patient might receive antispasmodics, particularly atropine, to allow the passage of the foreign body. Atropine in doses of $\frac{1}{400}$ or $\frac{1}{600}$ grain (0.16 or 0.1 mg.) administered three times daily might prove distinctly beneficial.

ANESTHETIC ACTION OF MAGNESIUM SULFATE

To the Editor:—It has been claimed that a 0.75 per cent solution of magnesium sulfate in water, injected around nerves or nerve roots, results in a prolonged anesthesia. 1. Is this claim well proved and generally accepted? 2. Could any possible harm result from the indiscriminate and wide use of 0.75 per cent magnesium sulfate solution as a solvent for the commonly used local anesthetics such as procaine and metycaine instead of water or saline solution?

Heinrich Lomm, M.D., La Feria, Texas.

ANSWER.—1. No.

2. S. J. Meltzer (*Berl. klin. Wchschr.* 1:73, 1906) experimented with this substance. He gave it subcutaneously, intravenously and intraspinally. He injected 1 cc. of a 25 per cent sterile solution of magnesium sulfate for each 12 Kg. of body weight and found that after three to four hours it was possible to operate painlessly on the legs and pelvic regions. He concluded that general anesthesia may often be produced by the intraspinal and subcutaneous injection of magnesium sulfate. From these experiments it appears that the use of a 0.75 per cent solution of magnesium sulfate as a solvent for the common local anesthetic agents might prolong the anesthesia, but the indiscriminate use of this solution would probably produce cerebral depression and a resultant general anesthesia.

Meltzer and Auer (*J. Exper. Med.* 123:641, 1916) stated that the application of solutions of magnesium salts to nerve trunks interrupted conduction. A more or less complete block for afferent and efferent, for normal or artificial, impulses was established. This could be accomplished by hypertonic, isotonic and hypotonic solutions. The more concentrated the solution, the sooner the effect was established. In general, it takes more time for magnesium solutions to cause block of a nerve trunk than for other known local or general anesthetics.

DISINFECTION OF BARBERS' INSTRUMENTS AND STOCKINGS

To the Editor:—What solution or solutions should be used to sterilize barbers' instruments or other instruments that could be a means of transmission of ringworm?

M.D., Iowa.

To the Editor:—Could you suggest a simple method of disinfecting stockings to destroy fungi—one that will not injure the stockings themselves? For your information, formaldehyde vapor removes the dye from nylon stockings.

M.D., California.

ANSWER.—1. The best means of sterilizing barbers' instruments is boiling them in sterile water. If this is not possible, they should be soaked in a 2 per cent cresol solution after being used on a person with ringworm of the scalp.

2. A dish of formaldehyde placed in a corner of a closed box and the stockings left in the box for twenty-four to forty-eight hours will generally kill the fungus. If the formaldehyde vapor removes the dye, the only thing that can be done is to wash the stockings repeatedly and thoroughly in soap and water.

TINGLING OF SHOULDER AND CERVICAL RIB

To the Editor:—A man awakened with a stiff neck after sleeping in a constrained position with his head bent over to the left. Later that day he had a tingling sensation in the left subclavicular fossa, similar to a galvanic treatment, which later had a sensation of being faradized almost to the point of a tetanic reaction. There is no particular pain, but the sensation "stops" him momentarily. Use of the left arm in an extended position seems to bring it on. In sleeping on the right side the tingling is felt and can be stopped by quickly lying on the left side. The shoulder first and can be stopped by x-rayed and nothing can be seen. The blood count and the chest have been x-rayed and nothing can be seen. The pressure is 185/110. The Wassermann reaction is negative for syphilis. The patient is otherwise in good physical condition. Is this a scalenus anticus syndrome?

M.D., Missouri.

ANSWER.—Careful x-rays should be taken of the cervical spine to be certain that the patient does not have a cervical rib. If one is found, it will have to be decided whether or not it is causing the complaint. Cervical ribs do not always cause trouble. It could be a scalenus anticus syndrome but certainly of an unusual type. The patient's hypertension should be taken into consideration in treatment.

THYROID, METHYL TESTOSTERONE AND IMPOTENCE

To the Editor:—Has any improvement in cases of impotence ever been ascribed to thyroid? Has any loss of potency ever followed the use of methyl testosterone?

M.D., Illinois

ANSWER.—If impotence is associated with a thyroid deficiency it may be improved by the administration of desiccated thyroid. This form of treatment is not effective in the absence of a thyroid deficiency. Information on any loss of potency following the use of methyl testosterone has not been found.

SULFADIAZINE RESISTANT STRAINS OF BETA HEMOLYTIC STREPTOCOCCI

APPEARANCE DURING THE COURSE OF SULFADIAZINE
PROPHYLAXIS AT A LARGE NAVAL TRAINING
CENTER

EPIDEMIOLOGY UNIT NUMBER 22

A previous paper has described the pronounced reduction of streptococcic disease which occurred at a large naval training center in the Northwest as the result of sulfadiazine prophylaxis.¹ The present report deals with the loss of effectiveness of this prophylaxis as the result of the appearance of sulfadiazine resistant strains.

On March 1, 1944 all personnel at the center were placed on sulfadiazine prophylaxis and no control studies were carried out. Shortly thereafter, during this month of March, there was a decided increase in streptococcic disease in Camp Hill, one of the recruit camps, which at the beginning of March had been on sulfadiazine prophylaxis for a period of approximately three months. Streptococcic infections were approximately four times as frequent as they were in January, when the drug had been most effective (table 1). Furthermore, during January only 22 per cent of admitted patients with respiratory illness had throat cultures positive for beta hemolytic streptococci, whereas in March 47 per cent of such patients had positive cultures. A similar rise occurred in April in all camps at the center, which was confirmed clinically and bacteriologically.

This outbreak was investigated in Camp Hill and in other areas during April. It was found that:

1. The increase was not due to failure of the recruits to take the drug or absorb it.
2. The increase had no relation to the length of time the camp had been on sulfadiazine.

Capt William P. Mull, senior medical officer of the center, cooperated and helped.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writers and are not to be considered as reflecting the policies of the Navy Department.

The members of Epidemiology Unit Number 22 during the period of this study were Donald C. Young, Comdr. (MC), U.S.N.R.; B. B. Breese, Comdr. (MC), U.S.N.R.; A. I. Errington, Comdr. (MC), U.S.N.R.; Walter Stoefler, Comdr. (MC), U.S.N.R.; Fred C. Zulse, Lns. (HC), U.S.N.; Russel R. Harrison, Ch Pharm. (HC), U.S.N.; Grove G. Wiley, Ch Pharm (HS), U.S.N.R.; Edward L. Warmanen, CPhM, U.S.N.R.; William D. Harrison, PHM 1c, U.S.N.R.; Carl E. Johnson, PHM 1c, U.S.N.R.; Louis E. Wagshol, PHM 1c, U.S.N.R.; Peter Packet, PHM 1c, U.S.N.R.; LeRoy V. Grussendorf, PHM 1c, U.S.N.R.; Alfred H. Rodger, PHM 2c, U.S.N.R.; Gene W. Johnston, PHM 2c, U.S.N.R.; Fred Elias, PHM 2c, U.S.N.R.; Jack Linder, PHM 2c, U.S.N.R.; Sam Pollock, PHM 2c, U.S.N.R., and Herbert Stevenson, PHM 3c, U.S.N.R.

1. The Prevention of Respiratory Tract Bacterial Infections by Sulfadiazine, U. S. Navy, Epidemiology Unit No. 22, Bureau of Medicine and Surgery, Navy Department, 734

3. At the same time the year before there had been a definite increase in streptococcic infections at the center.

4. A rising rate of streptococcic infection was reported by the Public Health Service in the country as a whole during this same period.

5. Crude tests on in vitro sulfadiazine resistance made in our laboratory without eliminating the sulfonamide inhibitors present in most mediums showed no evidence of sulfadiazine resistance.

For these reasons, and because no controlled study was being carried out, it was felt at that time that this rise was probably seasonal and not due to the development of sulfadiazine resistant strains.

However, in May the results of the typing of the streptococci obtained from the patients in Camp Hill were reported from the National Naval Medical Center's Streptococcus Typing Center. A remarkable change had occurred in the distribution of group A beta hemolytic streptococci. Type 19 had, in the early part of the program, been responsible for approximately 28 per cent of the total group A streptococcic infections in Camp Hill. During April and May it was responsible for 95 per cent of such infections. This relative increase of the frequency of type 19 infections was later found to be general over the center (chart 1).

This predominance of one type and the disappearance of other types in the face of a rising rate of streptococcic disease in recruits who had been taking sulfadiazine prophylactically suggested that this organism had become relatively sulfadiazine resistant, and thus our earlier premise that the increase was seasonal was fallacious.

With the initiation of sulfadiazine prophylaxis, the possibility of the appearance of strains of beta hemolytic streptococci resistant to this drug was recognized. Lieut. Comdr. Armine Wilson had, for some time, been working on an in vitro test for resistance of streptococci. This test required the elimination of sulfonamide inhibitors present in all common mediums. Although modified to some extent later, it was perfected to the point where it could be applied by the early part of June. The technic of the test has been described elsewhere by Wilson.² It was based on the ability of streptococci to grow in a semisynthetic medium, relatively free of sulfonamide inhibitors, to which sodium sulfadiazine had been added to give a final concentration of 0, 1, 5, 25 and 125 mg. per hundred cubic centimeters of the drug. The resistance to sulfadiazine is measured by the ability of these concentrations to inhibit growth and was read accordingly. Thus, if a strain of streptococcus grew in tubes containing 0.1 and 5 mg. of sulfadiazine but did not grow in concentrations of 25 and 125 mg., the

2. Wilson, Armine T. Method for Testing In Vitro Resistance of Group A Hemolytic Streptococci to Sulfonamides, *Proc. Soc. Exper. Biol. & Med.* 58: 130-133, 1945

organism was said to have a resistance of 5 mg. of sulfadiazine.

A high percentage of cultures of types 19 and 17 streptococci obtained from this center in June were found to be resistant to concentrations of 25 and 125 mg. of sulfadiazine, but types other than these two, with an

occasional exception of type 3, did not have this ability and were not sulfonamide resistant. This fact gave direct laboratory evidence that sulfonamide resistance had appeared in two types of streptococci, 17 and 19, and supported the hypothesis that the predominance of the latter type and the occurrence of streptococcal disease in recruits taking sulfadiazine was due to the appearance of a sulfadiazine resistant strain of streptococcus. By June, the time at which the resistance tests were first done, type 17 was more common than it had been earlier, and later this type became more and more frequent (chart 1). Unfortunately, practically no strains isolated prior to June had been preserved. It seemed probable, nevertheless, that resistant strains of type 19 first became predominant during March and April and that similar resistant strains of type 17 become common subsequently.

That this was the first known appearance of strongly sulfadiazine resistant strains of beta hemolytic streptococci, at least in any numbers, was supported by the following additional facts:

1. This was the first time at this center or in any other naval activity where sulfadiazine prophylaxis had proved ineffective in controlling streptococcal infection.

2. One strain of type 17 and one of type 19 preserved from December 1943 at this same activity were not strongly sulfadiazine resistant. The type 17 showed a resistance to 5 mg. of sulfadiazine and the type 19 no resistance.

3. Of six strains of type 19 and five of type 17 streptococci preserved from Mrs. Lancefield's collection from the presulfonamide era, none were resistant.

4. Strains obtained during the summer of 1944 from other naval activities in the East, Middle West and Southwest, who received few men from this center but where sulfonamide prophylaxis had been carried out during the previous season, revealed no strongly resistant strains of streptococci (table 2).

In June and July the general sulfadiazine prophylactic program was discontinued. Four recruit camps, however, were continued on 0.5 Gm. doses of sulfadiazine given for a part of the training period. Although these studies were inconclusive as the result of lax administration of the tablets, there seemed to be some evidence that even at this time 0.5 Gm. doses of sulfadiazine had some, but slight, value in preventing streptococcal infection.

The streptococcal disease rate remained high through July, and, since so little was known of the role of sulfonamide resistant strains of beta hemolytic streptococci and their relationship to sulfadiazine prophylaxis in various doses, it was decided to continue studies despite the known presence of sulfonamide fast strains. Two camps, Waldron and Peterson, which for the period April through July had the highest overall streptococcal disease rates (table 3) were selected for continued prophylaxis, whereas the remaining three camps were to get no prophylaxis.

TABLE 3.—Comparison of Streptococcal Disease Rates in Five Recruit Camps from April to July Inclusive, Expressed as Annual Rate per Thousand

	Tonsillitis-Pharyngitis	Scarlet Fever	Combined
Waldron.....(A)	182	85	263
Ward.....(B)	82	65	180
Hennlon.....(C)	98	74	172
Hill.....(D)	136	90	226
Peterson.....(E)	197	101	298

Accordingly, in these two camps the even numbered companies were given 1.0 Gm. and the odd numbered companies 0.5 Gm. of sulfadiazine daily, starting August 7. An addition in personnel to the Epidemiology Unit made it possible to supervise the administration of the tablets, and within a short time compliance was practically perfect.

Approximately coincident with the administration of sulfadiazine in these two camps there was a rise in practically all types of respiratory illness throughout the center. In some areas the upward trend was apparent before the sulfadiazine was started, but in all areas, whether sulfadiazine was administered or not, there was an obvious increase in streptococcal infection, both absolute and relative in either August or September, which continued into October (charts 2, 3 and 4).

During August the two camps on sulfadiazine had the highest absolute attack rates for scarlet fever and tonsillitis-pharyngitis of any recruit areas. Furthermore, the admission rate of patients with positive throat cultures for hemolytic streptococci was also highest in these two camps. This high rate was maintained through September and most of October (left half of charts 2, 3 and 4). The relative increase in these diseases over that of July in the camps getting sulfadiazine compared with those not getting it was, however, neither as well defined nor as consistent as the absolute increase (right half of charts 2, 3 and 4). The most striking difference between the treated and untreated camps was the much higher rate of scarlet fever in the treated groups.

This was a complete reversal of the experience early in the program prior to the appearance of sulfadiazine resistant strains. Furthermore, there seemed to be no significant difference between the 0.5 and the 1.0 Gm. doses of prophylactic sulfadiazine in preventing strepto-

In the presence of this outbreak it seemed imperative to answer two questions:

1. If the blood level of sulfadiazine is increased by giving 1.5 Gm. of sulfadiazine daily, will sulfadiazine still fail as a prophylactic measure?

Chart 1—Distribution of types of hemolytic streptococci, 1944.

Chart 2.—Tonsillitis and pharyngitis, 1944.

coccic disease, neither dose having prophylactic value. In addition there was some suggestion from the high rates for scarlet fever in Camps Waldron and Peterson, compared with the lower rates in the untreated camps, that this dose might enhance the ability of the streptococcus to attack individuals getting the sulfadiazine.

2. If it does fail is there any evidence that the sulfadiazine at this dosage level increases the likelihood of acquiring streptococcic disease?

The camps used in attempting to answer these questions were Waldron, Peterson and Ward. The recruits in the first two of these camps had been receiving

sulfadiazine prophylaxis during August, as already mentioned, while in the third camp no sulfadiazine had been given for over a month. Waldron and Peterson had the highest streptococcus disease rates during August and Camp Ward the lowest rate. In each camp

due to camp age, location of barracks and similar variables. The administration was supervised carefully, and the men received the drug as ordered from September 13 until October 8, except in Camp Peterson, where the drug was discontinued on October 4. Three companies

Chart 3—Scarlet fever, 1944

Chart 4—Positive streptococci, 1944

the recruits in the odd numbered companies received no sulfadiazine, whereas those in the even numbered companies received 1.5 Gm. of the drug daily. Since odd and even numbered companies were admitted alternately into each recruit area, this was felt to give the best possible experimental pattern, eliminating bias

in Camp Waldron developed cases of diphtheria and streptococcal disease concomitantly during this period and were excluded from the study.

Despite the larger dose of sulfonamide, the outbreak continued in the treated individuals as well as in the controls. Clinical analysis of the blood of recruits receiv-

ing 1.5 Gm. of sulfadiazine indicated that in the majority of these men levels of at least 2 mg. per hundred cubic centimeters were reached daily. Furthermore, the three companies that had both diphtheria and streptococcal disease were given 2 Gm. of sulfadiazine daily from September 8 to October 4 inclusive, but despite this increased dose their rate for streptococcal infection was exceedingly high. It therefore became apparent that increasing the dose of sulfadiazine was not effective and that daily doses of 0.5, 1, 1.5 and 2 Gm. all seemed equally useless in controlling streptococcal disease.

The second question, whether, in the presence of sulfadiazine resistant strains, sulfadiazine prophylaxis enhanced the possibility of acquiring streptococcal disease could not be definitely answered. However, the evidence in favor of the stimulating effect of sulfadiazine on streptococcal illness in the presence of these sulfonamide resistant strains was as follows:

1. Concurrent with the institution of consistent administration of sulfadiazine in August, an outbreak of streptococcal infection occurred with a high proportion of cases of scarlet fever.

2. The attack rate for all types of streptococcal infection and particularly scarlet fever was greater in the treated than in the untreated camps at this time.

3. When one half of a camp (even numbered companies) were given 1.5 Gm. of sulfadiazine and the other half (odd numbered companies) received none, more streptococcal disease usually occurred in the companies receiving the sulfadiazine (table 4).

It was shown that these higher rates in the treated companies as a whole were not due to previous differences in illness rates or to a few treated companies with very high rates.

On the other hand, there were a considerable number of facts which prevented any definite conclusions on this enhancing or stimulating effect:

The fact that a streptococcus outbreak occurred when sulfadiazine prophylaxis was being given had little value in proving that the one was influenced by the other, for the following reasons:

(a) In retrospect there was some evidence that the streptococcus rate was beginning to rise in late July and the first week of August before the intensive sulfadiazine program was reinstituted. In the previous summer a similar but smaller rise began at this time of year.

(b) During the summer the training period of recruits had been increased from six to twelve weeks, thus allowing more time for an outbreak in any given company to gain momentum.

(c) During June and July the mean age of recruits had decreased, thus increasing the number of younger and more susceptible recruits.

(d) One of the two dispensaries in each camp had been closed, resulting in greater opportunity for more cross infection at sick call and in the wards.

(e) The rise in streptococcal disease rates was general throughout the camp, whether sulfadiazine prophylaxis was administered or not.

The fact that the rates were higher, particularly for scarlet fever, in the treated camps than in the untreated camps was not too significant, since:

(a) The two camps selected had had the highest streptococcal disease rates for a period of five months of any of the recruit camps and it would be expected

that this circumstance, whatever its cause, would continue under epidemic conditions.

(b) Camps, being relatively isolated from one another, in the face of an outbreak act as individuals, and a conclusion based on 2 treated individuals and 3 controls carries little weight.

It was hoped that, by dividing each camp into two equal and apparently comparable groups and giving one sulfadiazine and the other no sulfadiazine, conclusive evidence could be obtained indicating whether the prophylaxis had an enhancing effect on streptococcal disease.

The evidence seemed compatible with this hypothesis but was neither consistent enough nor carried over a

long enough period of time to be conclusive. Although the rates for tonsillitis-pharyngitis, scarlet fever and total admissions of patients with positive throat cultures for hemolytic streptococci was greater in the treated groups than in the untreated groups when the figures for the three camps were combined, there was a lack of consistency in the results when the figures for the three camps were considered individually. Although in each camp the scarlet fever rate was higher in the treated group than in the untreated group, in Camp Peterson the tonsillitis-pharyngitis and total patients admitted with positive cultures for beta hemolytic streptococci was higher, although not significantly, in the untreated companies than in the treated companies (table 4).

In the presence of both nonresistant and sulfonamide resistant strains, it would be expected that sulfadiazine prophylaxis would tend to inhibit the nonresistant strains and not have the same effect on the resistant strains. The resulting effect would be that, as in Camp Hill in April, the resistant strains would become predominant and the nonresistant strains would disappear. This was confirmed by the fact that not only were the types which developed pronounced resistance (types 17 and 19) more common in areas where sulfonamide was used (table 5) but that the proportion of resistant strains of types 17 and 19 were also more common in these areas (table 6) than in the untreated areas.

It would also be expected that resistance would be most likely to appear in the more widespread and

therefore presumably more communicable types. This seemed true since types 17 and 19 had been, at the beginning of the sulfadiazine program, most frequently found, whereas type 3, which had shown some evidence of resistance, had been next most common. Additional evidence that these types which showed sulfadiazine resistance were also quite communicable was found in the fact that during the summer of 1944 several other naval activities on the West Coast that received trainees from our center regularly had evidence of infection with these same sulfadiazine resistant strains (table 7). Other camps that received few trainees from our center had little evidence of infection with these resistant strains (table 2).

In addition, these three types in which resistance appeared were characterized by their ability to form erythrogenic toxin. This ability was, however, apparently independent of whether they were resistant or not, as evidenced by the fact that types 17, 19 and 3

before resistance could be demonstrated had shown more tendency to cause scarlet fever than any other type present at the center. Thus, in January and February of 1944, 45 per cent of the most common respiratory infections (catarrhal fever, tonsillitis-pharyngitis and scarlet fever) caused by type 3, 46 per cent caused by type 17 and 26 per cent caused by type 19 were scarlet fever. Furthermore, with the appearance of resistance to sulfadiazine, this ability to cause scarlet fever decreased slightly in type 17 but increased in type 19. Thus, in August and September, when most type 17 and type 19 organisms were resistant, 34 per cent of the common respiratory infections caused by type 17 and 42 per cent of those due to type 19 were scarlet fever.

It was therefore clear that the strains of types 17 and 19 which caused trouble in August and September had three apparently independent attributes in common—they were sulfadiazine resistant not only to prophylactic but, according to the medical officers at the hospital, to therapeutic dosage as well, they were highly communicable and they formed erythrogenic toxin. They also had the additional attributes of being able to invade tissue giving rise to suppurative lesions, and the ability to cause rheumatic fever. Whether these last two characteristics were greater in the sulfonamide resistant strains than they were in the nonresistant strains is not known.

COMMENT

From the experience in the initial months of the sulfadiazine prophylaxis program there seemed no doubt that this measure was effective in controlling streptococcal disease in the presence of sulfadiazine sensitive strains. Later it became equally clear that, in the presence of sulfadiazine resistant strains, prophylaxis with sulfadiazine was of no value and was possibly injurious.

This center was the first place, to our knowledge, where clinically important sulfadiazine resistant strains of beta hemolytic streptococci appeared. It had, at the onset of the sulfadiazine program, an exceedingly high rate of streptococcal disease—much higher than any other comparable training center. With the original high infection rate, the continuous influx of new strains and the thousands of generations of streptococci in a changing population, the potentialities of having a rare resistant strain brought in, or a mutation in the direction of resistance occur in the strains already present were great.

Under conditions of mass sulfadiazine prophylaxis or treatment, Darwin's phenomenon of "survival of the fittest" would tend to eliminate the less resistant strains. The result would be, as we found originally in Camp Hill and later in the center as a whole, that the resistant strains would become predominant, provided they also had the potentiality of high communicability. In this military camp, where new susceptibles were introduced continuously and were given prophylaxis the biologic result was therefore the relative increase in the number of strains that were both sulfonamide resistant and highly communicable. These strains formed incidentally, potent erythrogenic toxin, thus giving rise to a higher proportion of cases of scarlet fever to total streptococcal disease than earlier in the year (36 per cent in September 1944, compared with 22 per cent in January 1944).

Whether in the presence of sulfadiazine resistant strains prophylaxis tends to increase streptococcal infec-

tions is, on the basis of our experience, impossible to answer. We have shown that the two highly resistant strains of types 17 and 19, as well as the less resistant type 3, had, even before the appearance of resistance, been more likely to cause scarlet fever than the other types of streptococci which were present at the center. Since the sulfadiazine prophylaxis inhibited the non-resistant types, which at this center were less likely to cause scarlet fever, an outbreak occurring in a regimental area or camp where prophylaxis is given would be characterized by a higher proportion of cases of scarlet fever than in an area where an equal amount of streptococcal infection occurred as the result of a combination of resistant and nonresistant strains. This might explain the apparently higher rate of scarlet fever in treated groups. It does not, however, account for the apparently higher attack rate for total streptococcal disease in a group getting sulfadiazine than in a control group not getting the drug, a condition which occurred in two of the three camps included in the study in late September and early October. If these differences were real and not the result of some chance or systematic error of unknown nature, these phenomena might be explained in a number of ways. Among these theories one could suggest:

1. That the sulfadiazine resistant strains had so altered their enzyme systems that sulfadiazine in small concentrations in the host acted as an added growth factor or a catalytic agent.

2. That sulfadiazine inhibits certain organisms in the throat which normally compete with the streptococcus for food requirements or produce substances which have an antibiotic effect on the beta hemolytic streptococcus.

But, leaving theories to explain unproved observations aside, the fact remains that the appearance of sulfadiazine resistant strains of beta hemolytic streptococci completely sabotaged an effective means of control of respiratory infections at this center.

SUMMARY

After approximately three months of successful sulfadiazine prophylaxis of respiratory infections at a large naval training center, the effectiveness of this measure became progressively less and eventually a major epidemic of streptococcal disease occurred.

An increase in dosage as high as 2 Gm. daily did not prevent streptococcal diseases, and it was the impression of medical officers at the center that the drug had lost its value therapeutically in these infections.

The loss of prophylactic value of sulfadiazine was originally associated with an absolute and relative increase in the frequency of group A, type 19 infections to the practical exclusion of all other types. Later, group A, type 17 became relatively frequent. These two types were shown by laboratory methods to be sulfonamide resistant *in vitro*.

Other types of streptococci with a few exceptions of type 3 were not sulfonamide resistant.

The proportion of sulfadiazine resistant strains was greater in those recruit camps getting sulfadiazine prophylaxis than in those not getting sulfadiazine.

There was some suggestive evidence but no definite proof that, in the presence of sulfadiazine resistant strains, sulfadiazine prophylaxis tended to increase streptococcal infection, particularly scarlet fever.

THE DEVELOPMENT AND USE OF ALPHA-NAPHTHYL THIOUREA (ANTU) AS A RAT POISON

CURT P. RICHTER, PH.D.

BALTIMORE

During the past three years an investigation has been carried on in this laboratory with the purpose of finding and developing a new rat poison. The best poison so found, alpha-naphthyl thiourea (ANTU), has been proved through extensive laboratory tests and also by controlled field trials in a large city to be an effective and specific poison for the Norway rat, a very common and destructive rat throughout the world.

Since secrecy restrictions on this work have now been lifted and the Office of Scientific Research and Development has given permission for the manufacture and release of alpha-naphthyl thiourea to the public, it seems advisable to present an account of the development of this poison together with effective ways of using it, its toxicity to animals other than rats and procedures to be followed in case of accidental poisoning. The experience gained by large scale field use of alpha-naphthyl thiourea is summarized as a guide to those who have occasion to conduct organized eradication campaigns in the future.

It may be mentioned at this time that, quite apart from rodenticidal uses, alpha-naphthyl thiourea and other thiourea derivatives have proved to be interesting and useful new agents in fields as varied as medicine, biochemistry, physiology and genetics.

Interest in thiourea derivatives as rat poisons arose indirectly from studies on the self selection of diets, which showed rats to be capable of choosing nutritive substances and avoiding harmful ones.¹ This ability to make beneficial dietary selections was found to be lost when taste nerves were sectioned;² accordingly it was concluded that some connection exists between the taste of substances and their nutritional or toxic values.

To test this theory the toxicity of various bitter substances was determined. One very bitter substance which had been considered nontoxic was phenyl thiourea (also known as phenyl thiocarbamide). Since the observation of Fox in 1931 that, while this compound tasted very bitter to most people there were some who could not taste it at all,³ phenyl thiourea had been widely used for research in the fields of genetics and sensory perception. (The inability to taste phenyl thiourea was found⁴ to be inherited as a mendelian recessive.)

Following the usual method of testing taste ability in human beings with phenyl thiourea, we placed a few crystals on the tongues of 6 rats. To our surprise all 6 were found dead the next morning. This observation was followed up by a quantitative determination of the

From the Psychobiological Laboratory, Phipps Psychiatric Clinic, the Johns Hopkins Hospital.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and the Johns Hopkins University.

This work was done with the collaboration of Miss Nancy Cadwalader, Mrs. K. C. Clisby, Dr. S. H. Dieke, Dr. J. T. Emlen Jr., Dr. James Flexner, Dr. J. B. Iverichs, Dr. W. J. Griffiths Jr. and Mrs. Martha Schaffer.

toxicity to our stock rats. The median lethal dose was found to be 3 or 4 mg. per kilogram of body weight; in other words phenyl thiourea was quite as toxic to rats as strychnine!

In the course of our work on the toxic effects of phenyl thiourea,⁵ it was found that our laboratory rats regularly ate enough poisoned food to kill themselves when offered with concentrations of phenyl thiourea as low as 1 per cent. It thus appeared that this highly poisonous substance might be accepted well enough to make it useful as a rat poison.
